

## Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32L151xx and STM32L152xx microcontroller memory and peripherals. The STM32L151xx and STM32L152xx will be referred to as STM32L15xxx throughout the document, unless otherwise specified.

The STM32L15xxx is a family of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical and electrical device characteristics please refer to the *STM32L151xx and STM32L152xx* datasheet.

For information on programming, erasing and protection of the internal Flash memory please refer to the *STM32L15xxx Flash programming manual*.

For information on the ARM Cortex™-M3 core, please refer to the *Cortex™-M3 Technical Reference Manual*.

## 1.1 List of abbreviations for registers

The following abbreviations are used in register descriptions:

read/write (rw)	Software can read and write to these bits.
read-only (r)	Software can only read these bits.
write-only (w)	Software can only write to this bit. Reading the bit returns the reset value.
read/clear (rc_w1)	Software can read as well as clear this bit by writing 1. Writing '0 has no effect on the bit value.
read/clear (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to '0. Writing '0 has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing '0 has no effect on the bit value.
read-only write trigger (rt_w)	Software can read this bit. Writing '0 or '1 triggers an event but has no effect on the bit value.
toggle (t)	Software can only toggle this bit by writing '1. Writing '0 has no effect.
Reserved (Res.)	Reserved bit, must be kept at reset value.

## 1.2 Peripheral availability

For the peripherals available, and their number, across all STM32L15xxx sales types, please refer to the STM32L15xxx datasheet.

## 2 Memory and bus architecture

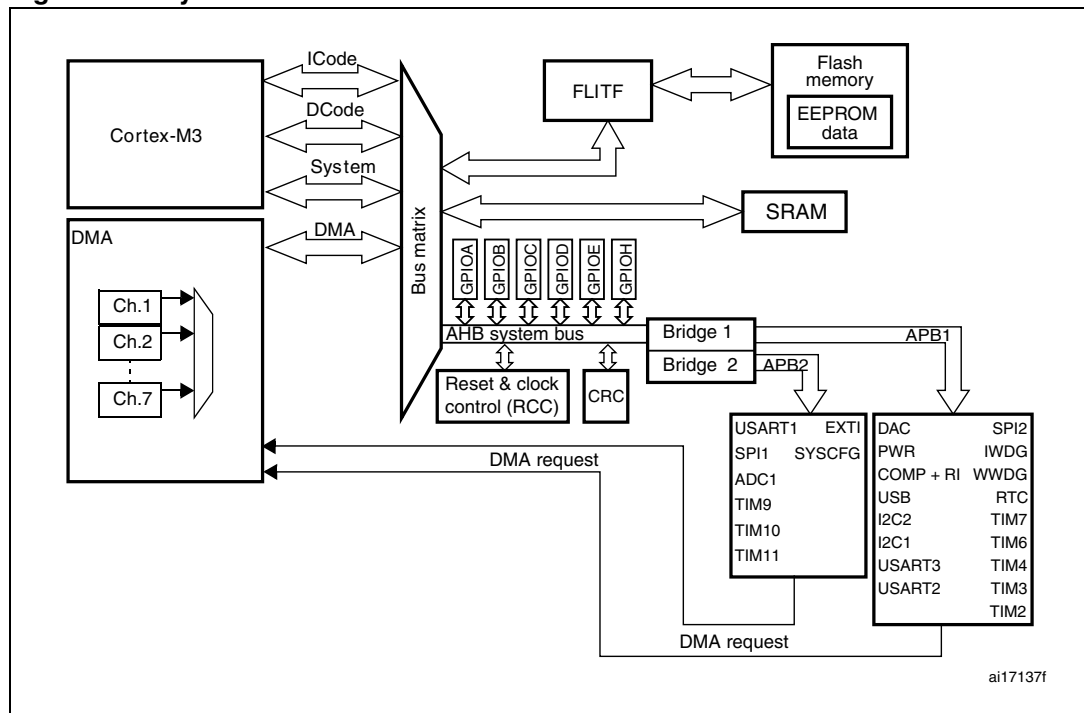

### 2.1 System architecture

The main system consists of a 32-bit multilayer AHB bus matrix that interconnects:

- Four masters:
  - Cortex-M3 I-bus, D-bus and S-bus
  - DMA
- Three slaves:
  - Internal Flash memory
  - Internal SRAM
  - AHB to APBx (APB1 or APB2), which connect all the APB peripherals

These are interconnected using the multilayer AHB bus architecture shown in *Figure 1*:

**Figure 1. System architecture**

#### ICode bus

This bus connects the Instruction bus of the Cortex-M3 core to the BusMatrix. This bus is used by the core to fetch instructions. The target of this bus is a memory containing code (internal Flash memory or SRAM).

#### DCode bus

This bus connects the databus of the Cortex-M3 to the BusMatrix. This bus is used by the core for literal load and debug access. The target of this bus is a memory containing code or data (internal Flash memory or SRAM).

#### System bus

This bus connects the system bus of the Cortex-M3 core to a BusMatrix. This bus is used to access data located in a peripheral or in SRAM. Instructions may also be fetched on this bus (less efficient than ICode). The targets of this bus are the internal SRAM and the AHB/APB bridges.

#### **DMA bus**

This bus connects the AHB master interface of the DMA to the bus matrix which manages the access of the CPU DCode and DMA to the SRAM, Flash memory and peripherals.

#### **Bus matrix**

The bus matrix manages the access arbitration between the core system bus and the DMA master bus. The arbitration uses a round robin algorithm. The bus matrix is composed of four masters (ICode, DCode, System bus, DMA1 bus, ) and three slaves (Flash interface, SRAM, FSMC, AES and AHB2APB bridges).

AHB peripherals are connected on the system bus through the bus matrix to allow DMA access.

#### **AHB/APB bridges (APB)**

The two AHB/APB bridges provide full synchronous connections between the AHB and the 2 APB buses. The two APB buses operates at full speed (up to 32 MHz).

Refer to [Table 1 on page 32](#) for the address mapping of the AHB and APB peripherals.

After each device reset, all peripheral clocks are disabled (except for the SRAM and Flash interface). Before using a peripheral, its clock should be enabled in the RCC\_AHBENR, RCC\_APB1ENR or RCC\_APB2ENR register.

*Note:* When a 16- or 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.

## **2.2 Memory organization**

Flash program memory, EEPROM data memory, SRAM data memory, registers and I/O ports are organized within the same linear 4 Gbyte address space.

The bytes are coded in memory in little endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte, the most significant.

For the detailed mapping of peripheral registers, please refer to the related sections.

The addressable memory space is divided into 8 main blocks, each of 512 Mbytes.

All the memory areas that are not allocated to on-chip memories and peripherals are considered "Reserved"). Refer to the memory map figure in the STM32L15xxx datasheet.

## **2.3 Memory map**

See the STM32L15xxx datasheet for a comprehensive diagram of the memory map. [Table 1](#) gives the boundary addresses of the peripherals available in all STM32L15xxx devices.

**Table 1. Register boundary addresses**

Boundary address	Peripheral	Bus	Register map
0xA000 0000 - 0xA000 0FFF	FSMC	AHB	<a href="#">Section 24.6.9: FSMC register map on page 651</a>

### 2.3.1 Embedded SRAM

The STM32L15xxx features 16 Kbytes of SRAM. It can be accessed as bytes, half-words (16 bits) or full words (32 bits). The SRAM start address is 0x2000 0000.

Read and write access at CPU speed with 0 wait states.

The CPU can access the SRAM through the system bus or through the I-Code/D-Code bus when boot in SRAM is selected or when physical remap is selected (see [Section 6.5.1: SYSCFG memory remap register \(SYSCFG\\_MEMRMP\)](#) register in the SYSCFG controller). To get the best SRAM execution performance, physical remap must be selected (boot or software selection).

### 2.3.2 Bit banding

The Cortex-M3 memory map includes two bit-band regions. These regions map each word in an alias region of memory to a bit in a bit-band region of memory. Writing to a word in the alias region has the same effect as a read-modify-write operation on the targeted bit in the bit-band region.

In the STM32L15xxx both the peripheral registers and the SRAM are mapped in a bit-band region. This allows single bit-band write and read operations to be performed. These operations are only available for cortex-M3 accesses, not from other bus masters (e.g. DMA).

A mapping formula shows how to reference each word in the alias region to a corresponding bit in the bit-band region. The mapping formula is:

$$bit\_word\_addr = bit\_band\_base + (byte\_offset \times 32) + (bit\_number \times 4)$$

where:

*bit\_word\_addr* is the address of the word in the alias memory region that maps to the targeted bit

*bit\_band\_base* is the start address of the alias region

*byte\_offset* is the number of the byte in the bit-band region, that contains the targeted bit

*bit\_number* is the bit position (0-7) of the targeted bit

#### Example:

The following example shows how to map bit 2 of the byte located at SRAM address 0x2000 0300 in the alias region:

$$0x2200\ 6008 = 0x2200\ 0000 + (0x300 \times 32) + (2 \times 4)$$

Writing to address 0x2200 6008 has the same effect as a read-modify-write operation on bit 2 of the byte at SRAM address 0x2000 0300.

Reading address 0x22006008 returns the value (0x01 or 0x00) of bit 2 of the byte at SRAM address 0x20000300 (0x01: bit set; 0x00: bit reset).

For more information on bit-banding, please refer to the *Cortex-M3 Technical Reference Manual*.

### 2.3.3 Embedded Flash memory

- Up to 132 Kbytes of Flash memory
- Memory organization (dual banks):
  - 128 Kbytes of Flash program memory and 412 Kbytes of data EEPROM
  - 4 Kbytes of system memory and 32 bytes of option bytes

Flash memory interface (FLITF) features:

- Flash memory read operations: read access is performed by 64 or 32 bits
- Flash memory program/erase operations
- Read/write protection
- Write access is performed by 32 bits
- Option byte loader reset
- Low power mode:
  - Flash memory in Power down mode when the STM32L15xxx is in the Standby mode or the Stop mode
  - Flash memory can be placed in Power down or Idle mode when the STM32L15xxx is in the Sleep mode
  - Flash memory can be placed in Power down or Idle mode when the STM32L15xxx is in the Run mode

**Flash module organization**

The memory is organized as a main program memory block, a data memory block of 512 double words, and an information block. [Table 2](#) shows the Flash memory organization.

The program memory block is divided into 32 sectors of 4 Kbytes each, and each sector is further split up into 16 pages of 256 bytes each. The sector is the write protection granularity. In total, the program memory block contains 512 pages.

**Table 2. Flash module organization**

Block	Flash memory addresses	Size	Name	Description
Program memory	0x0800 0000 - 0x0800 00FF	256 bytes	Page 0	Sector 0
	0x0800 0100 - 0x0800 01FF	256 bytes	Page 1	
	0x0800 0200 - 0x0800 02FF	256 bytes	Page 2	
	0x0800 0300 - 0x0800 03FF	256 bytes	Page 3	
	0x0800 0400 - 0x0800 07FF	1 Kbytes	Page 4 to 7	
	0x0800 0800 - 0x0800 0BFF	1 Kbytes	Page 8 to 11	
	0x0800 0C00 - 0x0800 0FFF	1 Kbytes	Page 12 to 15	
	0x0800 1000 - 0x0800 1FFF	4 Kbytes	Page 16 to 31	Sector 1
	0x0800 2000 - 0x0800 2FFF	4 Kbytes	Page 32 to 47	Sector 2
	0x0800 3000 - 0x0800 3FFF	4 Kbytes	Page 48 to 63	Sector 3
	.	.	.	.
	.	.	.	.
	.	.	.	.
	0x0801 E000 - 0x0801 EFFF	4 Kbytes	Page 478 to 495	Sector 30
0x0801 F000 - 0x0801 FFFF	4 Kbytes	Page 496 to 511	Sector 31	
Data memory	0x0808 0000 - 0x0808 0FFF	4096 bytes	DATA	Data memory

**Table 2. Flash module organization (continued)**

Block	Flash memory addresses	Size	Name	Description
Information Block	0x1FF0 0000 - 0x1FF0 00FF	256 bytes	Page 0	System memory
	0x1FF0 0100 - 0x1FF0 01FF	256 bytes	Page 1	
	0x1FF0 0200 - 0x1FF0 02FF	256 bytes	Page 2	
	0x1FF0 0300 - 0x1FF0 03FF	256 bytes	Page 3	
	.	.	.	
	.	.	.	
	0x1FF0 0F00 - 0x1FF0 0FFF	256 bytes	Page 15	
0x1FF8 0000 - 0x1FF8 001F	32 bytes	OPTB	Option bytes block	

**Reading the Flash memory**

**Relation between CPU clock frequency and Flash memory read time**

The Flash memory is read by 64 bits or 32 bits.

64-bit access is configured by setting the ACC64 bit in the Flash access control register (FLASH\_ACR). This access mode accelerates the execution of program operations. Prefetch is useful when the Flash memory cannot be accessed for a CPU cycle. In this case, the number of wait states (LATENCY) must be correctly programmed in the Flash access control register (FLASH\_ACR) according to the frequency of the Cortex-M3 clock and the supply voltage of the device. [Table 3](#) shows the correspondence between wait states and core clock frequency.

**Table 3. Number of wait states (WS) according to CPU clock (HCLK) frequency**

HCLK frequency (MHz)			Wait states (LATENCY)
Voltage range 1.65 V to 3.6 V		Voltage range 2.0 V to 3.6 V	
V <sub>CORE</sub> = 1.2 V	V <sub>CORE</sub> = 1.5 V	V <sub>CORE</sub> = 1.8 V	
0 < f <sub>HCLK</sub> ≤ 2 MHz	0 < f <sub>HCLK</sub> ≤ 8 MHz	0 < f <sub>HCLK</sub> ≤ 16 MHz	0 WS (1 HCLK cycle)
2 < f <sub>HCLK</sub> ≤ 4 MHz <sub>HCLK</sub>	8 < f <sub>HCLK</sub> ≤ 16 MHz	16 < f <sub>HCLK</sub> ≤ 32 MHz	1 WS (2 HCLK cycles)

It is also possible to access the Flash memory by 32 bits. This is done by clearing the ACC64 bit in FLASH\_ACR. In this case, prefetch has to be disabled. 32-bit access reduces the consumption, so it is used when the CPU frequency is low. In this case, the number of wait states must be 0.

After reset, the used clock is the MSI (2 MHz) with 0 WS configured in the FLASH\_ACR register. 32-bit access is enabled and prefetch is disabled.

ST strongly recommends to use the following software sequences to tune the number of wait states needed to access the Flash memory with the CPU frequency.

**Increasing the CPU frequency (in the same voltage range)**

- Program the 64-bit access by setting the ACC64 bit in *Flash access control register (FLASH\_ACR)*
- Check that 64-bit access is taken into account by reading FLASH\_ACR
- Program 1 WS to the LATENCY bit in FLASH\_ACR
- Check that the new number of WS is taken into account by reading FLASH\_ACR
- Modify the CPU clock source by writing to the SW bits in the *Clock configuration register (RCC\_CFGR)*
- If needed, modify the CPU clock prescaler by writing to the HPRE bits in RCC\_CFGR
- Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC\_CFGR register

**Decreasing the CPU frequency (in the same voltage range)**

- Modify the CPU clock source by writing to the SW bits in the *Clock configuration register (RCC\_CFGR)*
- If needed, modify the CPU clock prescaler by writing to the HPRE bits in RCC\_CFGR
- Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC\_CFGR register
- Program the new number of WS to the LATENCY bit in *Flash access control register (FLASH\_ACR)*
- Check that the new number of WS is taken into account by reading FLASH\_ACR
- Program the 32-bit access by clearing ACC64 in FLASH\_ACR
- Check that 32-bit access is taken into account by reading FLASH\_ACR

### Instruction prefetch when Flash access is 64 bits

Each Flash memory read operation provides 64 bits from either two 32-bit instructions or four 16-bit instructions. So, in case of a sequential code, at least 2 CPU cycles are needed to read the previous instruction line. Prefetch on the ICode bus can be used to read the next sequential instruction line from the Flash memory while the current instruction line is being requested by the CPU. Prefetch is enabled by setting the PRFTEN bit in the FLASH\_ACR register. This feature is useful if at least one wait state is needed to access the Flash memory.

[Table 4](#) shows the supported ACC64, LATENCY and PRFTEN configurations.

**Table 4. Allowed configuration in FLASH\_ACR**

LATENCY	ACC64 = 0		ACC64 = 1	
	PRFTEN = 0	PRFTEN = 1	PRFTEN = 0	PRFTEN = 1
0	OK	-	OK	OK
1	-	-	OK	OK

*Note:* The [Flash access control register \(FLASH\\_ACR\)](#) is used to control the Flash state in run/sleep modes, the prefetch status and access time depending on the CPU frequency. The table above provides the bit map for this register.

For complete information on Flash memory operations, please refer to the [STM32L15xxx Flash programming manual \(PM0062\)](#). For details on register configurations, refer to the following section ([Flash access control register \(FLASH\\_ACR\) on page 40](#)).

**Flash access control register (FLASH\_ACR)**

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																									RUN_PD	SLEEP_PD	ACC64	PRFTEN	LATENCY		
																									rw	rw	rw	rw	rw		

Bits 31:5 Reserved, must be kept cleared.

Bit 4 **RUN\_PD**: Flash mode during Run

This bit can be written only when it is unlocked by writing to FLASH\_PDKEYR.

This bit determines whether the Flash memory is in Power down mode or Idle mode when the STM32L15xxx is in Run mode.

The Flash memory can be placed in Power down mode only when the code is executed from RAM).

0: Flash in Idle mode

1: Flash in Power down mode

Bit 3 **SLEEP\_PD**: Flash mode during Sleep

This bit is used to have the Flash memory in Power down mode or Idle mode when the STM32L15xxx is in Sleep mode.

0: Flash in Idle mode

1: Flash in Power down mode

Bit 2 **ACC64**: 64-bit access

This bit is used to read data from the Flash memory 64 bits or 32 bits at a time. 32-bit access is used to decrease the Flash memory consumption. On the contrary, 64-bit access is used to improve the performance. In this case it is useful to enable prefetch.

0: 32-bit access

1: 64-bit access

*Note: 32-bit access is a low power mode. It is used only at low frequencies, that is with 0 wait state of latency and prefetch off.*

*Note: This bit cannot be written at the same time as the LATENCY and PRFTEN bits.*

Bit 1 **PRFTEN**: Prefetch enable

0: prefetch disabled

1: prefetch enabled

*Note: Prefetch can be enabled only when ACC64 is set.*

*This bit can be set or cleared only if ACC64 is set.*

Bit 0 **LATENCY**: Latency

This bit represents the ratio of the CPU clock period to the Flash access time.

0: zero wait state

1: one wait state

*Note: Latency can be set only when ACC64 is set.*

*This bit can be set or cleared only if ACC64 is set.*

### Flash interface register map

The following table summarizes the Flash memory registers.

**Table 5. Flash interface register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x00	FLASH_ACR	Reserved																								RUN_PD	SLEEP_PD	Acc64	PRFTEN	LATENCY0			
	Reset value: 0x0000 0000																									0	0	0	0	0			

## 2.4 Boot configuration

Due to its fixed memory map, the code area starts from address 0x0000 0000 (accessed through the ICode/DCode buses) while the data area (SRAM) starts from address 0x2000 0000 (accessed through the system bus). The Cortex-M3 CPU always fetches the reset vector from the ICode bus, which implies to have the boot space available only in the code area (typically, Flash memory). STM32L15xxx microcontrollers implement a special mechanism to be able to boot from other memory than the Flash (like internal SRAM).

In the STM32L15xxx, 3 different boot modes can be selected through the BOOT[1:0] pins as shown in [Table 6](#).

**Table 6. Boot modes**

Boot mode selection pins		Boot mode	Aliasing
BOOT1	BOOT0		
x	0	Main Flash memory	Main Flash memory is selected as the boot space
0	1	System memory	System memory is selected as the boot space
1	1	Embedded SRAM	Embedded SRAM is selected as the boot space

The values on the BOOT pins are latched on the 4th rising edge of SYSCCLK after a reset. It is up to the user to set the BOOT1 and BOOT0 pins after reset to select the required boot mode.

BOOT0 is a dedicated pin while BOOT1 is shared with a GPIO pin. Once BOOT1 has been sampled, the corresponding GPIO pin is free and can be used by the application.

The BOOT pins are also resampled when exiting the Standby mode. Consequently they must be kept in the required Boot mode configuration in Standby mode. After this startup delay has elapsed, the CPU fetches the top-of-stack value from address 0x0000 0000, then starts code execution from the boot memory starting from 0x0000 0004.

*Note: When booting from SRAM, in the application initialization code, you have to relocate the vector table in SRAM using the NVIC exception table and offset register.*

### Physical remap

When the boot pins are configured as desired, the application software can modify the memory accessible in the code area (code can thus be executed through the ICode/DCode

in place of the System bus). This modification is performed by programming the [SYSCFG memory remap register \(SYSCFG\\_MEMRMP\)](#) in the SYSCFG controller.

The following memory can then be remapped:

- Main Flash memory
- System memory
- Embedded SRAM

**Table 7. Memory mapping vs. boot mode/physical remap**

Addresses	Boot/Remap in main Flash memory	Boot/Remap in embedded SRAM	Boot/Remap in System memory
0x2000 0000 - 0x2000 3FFF	SRAM	SRAM	SRAM
0x1FF0 0000 - 0x1FF0 0FFF	System memory	System memory	System memory
0x0802 0000 - 0x0FFF FFFF	Reserved	Reserved	Reserved
0x0800 0000 - 0x0801 FFFF	Flash memory	Flash memory	Flash memory
0x0002 0000 - 0x07FF FFFF	Reserved	Reserved	Reserved
0x0000 0000 - 0x0001 FFFF	Flash (128 KB) Aliased	SRAM Aliased	System memory (4 KB) Aliased

*Note:* Even when aliased in the boot memory space, the related memory is still accessible at its original memory space.

**Embedded boot loader**

The embedded boot loader is used to reprogram the Flash memory through one of the following interfaces: USART1 or USART2. This program is located in the system memory and is programmed by ST during production.

## 3 Power control (PWR)

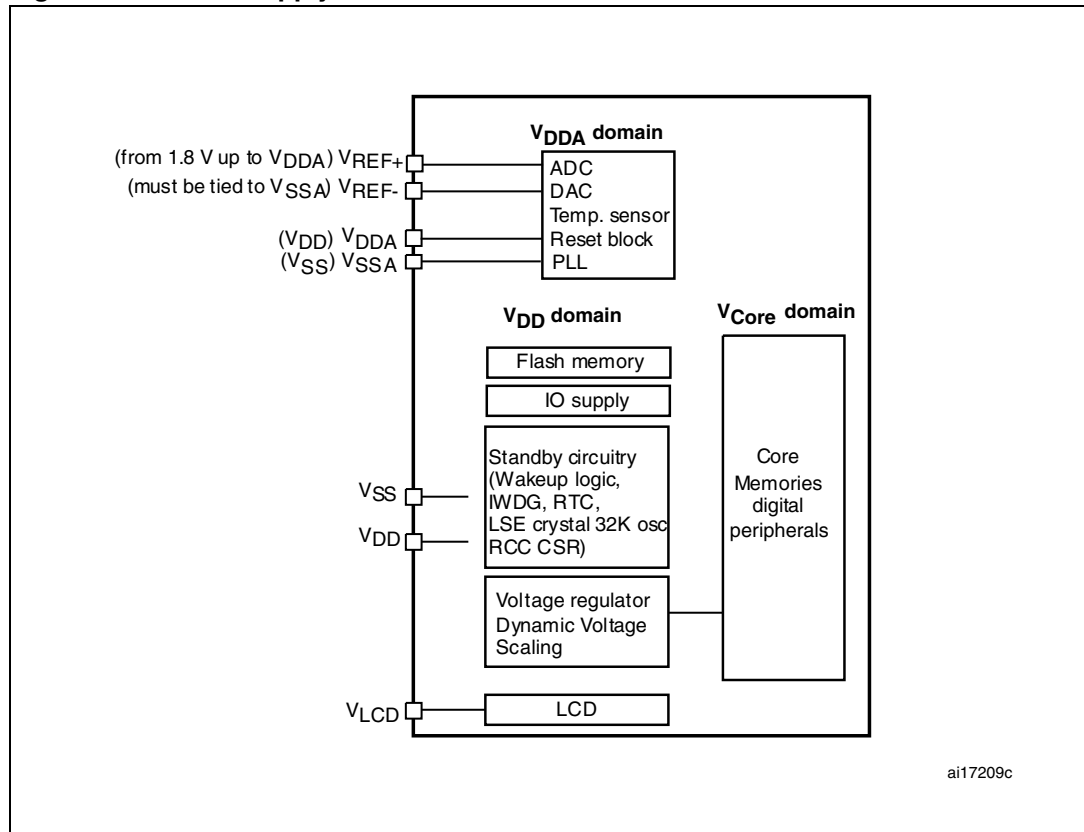

### 3.1 Power supplies

The device requires a 1.8-to-3.6 V  $V_{DD}$  operating voltage supply (down to 1.65 V at power down) when the BOR is available. The device requires a 1.65-to-3.6 V  $V_{DD}$  operating voltage supply when the BOR is not available.

An embedded linear voltage regulator is used to supply the internal digital power, ranging from 1.2 to 1.8 V.

- $V_{DD} = 1.8$  V (at power on) or 1.65 V (at power down) to 3.6 V when the BOR is available.  $V_{DD} = 1.65$  V to 3.6 V, when BOR is not available  
 $V_{DD}$  is the external power supply for I/Os and internal regulator. It is provided externally through  $V_{DD}$  pins
- $V_{CORE} = 1.2$  to 1.8 V  
 $V_{CORE}$  is the power supply for digital peripherals, SRAM and Flash memory. It is generated by a internal voltage regulator. Three  $V_{CORE}$  ranges can be selected by software depending on  $V_{DD}$  (refer [Figure 3](#)).
- $V_{SSA}, V_{DDA} = 1.8$  V (at power on) or 1.65 V (at power down) to 3.6 V, when BOR is available and  $V_{SSA}, V_{DDA} = 1.65$  to 3.6 V, when BOR is not available.  
 $V_{DDA}$  is the external analog power supply for ADC, DAC, reset blocks, RC oscillators and PLL. The minimum voltage to be applied to  $V_{DDA}$  is 1.8 V when the ADC is used.
- $V_{REF-}, V_{REF+}$   
 $V_{REF+}$  is the input reference voltage.  
 $V_{REF-}$  and  $V_{REF+}$  are only available as external pins on LQFP100 package, UFBGA100 and TFBGA64, otherwise they are bonded to  $V_{SSA}$ .
- $V_{LCD} = 2.5$  to 3.6 V  
The LCD controller can be powered either externally through  $V_{LCD}$  pin, or internally from an internal voltage generated by the embedded step-up converter.

Figure 2. Power supply overview

1. V<sub>DDA</sub> and V<sub>SSA</sub> must be connected to V<sub>DD</sub> and V<sub>SS</sub>, respectively.
2. When available (depending on packages), V<sub>REF-</sub> must be tied to V<sub>SSA</sub>.
3. Depending on the operating power supply range used, some peripherals may be used with limited functionalities or performance. For more details, please refer to section "General operating conditions" in STM32L15xxx datasheets.

### 3.1.1 Independent A/D and DAC converter supply and reference voltage

To improve conversion accuracy, the ADC and the DAC have an independent power supply that can be filtered separately, and shielded from noise on the PCB.

- The ADC voltage supply input is available on a separate V<sub>DDA</sub> pin
- An isolated supply ground connection is provided on the V<sub>SSA</sub> pin

### On BGA 64-pin and all 100-pin packages

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to  $V_{REF+}$  a separate external reference voltage lower than  $V_{DD}$ .  $V_{REF+}$  is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

- For ADC
  - $2.4\text{ V} \leq V_{REF+} = V_{DDA}$  for full speed (ADCCLK = 16 MHz, 1Msps)
  - $1.8\text{ V} \leq V_{REF+} = V_{DDA}$  for medium speed (ADCCLK = 8 MHz, 500 Ksps)
  - $2.4\text{ V} \leq V_{REF+} \neq V_{DDA}$  for medium speed (ADCCLK = 8 MHz, 500 Ksps)
  - $1.8\text{ V} \leq V_{REF+} < V_{DDA}$  for low speed (ADCCLK = 4 MHz, 250 Ksps)
  - When Product voltage range 3 is selected ( $V_{Core} = 1.2\text{ V}$ ) the ADC is low speed (ADCCLK = 4 MHz, 250 Ksps)
- For DAC
  - $1.8\text{ V} \leq V_{REF+} < V_{DDA}$
- When  $V_{DDA}$  is higher than 2.4 V, the voltage on  $V_{REF+}$  may range from 2.4 V to  $V_{DDA}$ .
- When  $V_{DDA}$  is below 2.4 V,  $V_{REF+}$  must be equal to  $V_{DDA}$ .

### On packages with 64 pins or less (except BGA package)

$V_{REF+}$  and  $V_{REF-}$  pins are not available. They are internally connected to the ADC voltage supply ( $V_{DDA}$ ) and ground ( $V_{SSA}$ ).

### 3.1.2 Independent LCD supply

The  $V_{LCD}$  pin is provided to control the contrast of the glass LCD. This pin can be used in two ways:

- It can receive from an external circuitry the desired maximum voltage that is provided on segment and common lines to the glass LCD by the microcontroller.
- It can also be used to connect an external capacitor that is used by the microcontroller for its voltage step-up converter. This step-up converter is controlled by software to provide the desired voltage to segment and common lines of the glass LCD.

The voltage provided to segment and common lines defines the contrast of the glass LCD pixels. This contrast can be reduced when you configure the dead time between frames.

- When an external power supply is provided to the  $V_{LCD}$  pin, it should range from 2.5 V to 3.6 V. It does not depend on  $V_{DD}$ .
- When the LCD is based on the internal step-up converter, the  $V_{LCD}$  pin should be connected to a capacitor (see the product datasheets for further information).

### 3.1.3 RTC and RTC backup registers

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar, two programmable alarm interrupts, and a periodic programmable wakeup flag with interrupt capability. The RTC contains 20 backup data registers (80 bytes) which are reset when a tamper detection event occurs. For more details refer to *Real-time clock (RTC)* section.

### RTC registers access

After reset, the RTC Registers (RTC registers and RTC backup registers) are protected against possible stray write accesses. To enable access to the RTC Registers, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the RCC\_APB1ENR register.
2. Set the DBP bit in the PWR\_CR register (see [Section 3.4.1](#)).
3. Select the RTC clock source through RTCSEL[1:0] bits in RCC\_CSR register.
4. Enable the RTC clock by programming the RTCEN bit in the RCC\_CSR register.

### 3.1.4 Voltage regulator

An embedded linear voltage regulator supplies all the digital circuitries except for the Standby circuitry. The regulator output voltage ( $V_{CORE}$ ) can be programmed by software to three different ranges within 1.2 - 1.8 V (typical) (see [Section 3.1.5](#)).

The voltage regulator is always enabled after Reset. It works in three different modes: main (MR), low power (LPR) and power down, depending on the application modes.

- In Run mode, the regulator is main (MR) mode and supplies full power to the  $V_{CORE}$  domain (core, memories and digital peripherals).
- In Low power run mode, the regulator is in low power (LPR) mode and supplies low power to the  $V_{CORE}$  domain, preserving the contents of the registers and internal SRAM.
- In Sleep mode, the regulator is main (MR) mode and supplies full power to the  $V_{CORE}$  domain, preserving the contents of the registers and internal SRAM.
- In low power sleep mode, the regulator is in low power (LPR) mode and supplies low power to the  $V_{CORE}$  domain, preserving the contents of the registers and internal SRAM.
- In Stop mode the regulator supplies low power to the  $V_{CORE}$  domain, preserving the content of registers and internal SRAM.
- In Standby mode, the regulator is powered off. The content of the registers and SRAM are lost except for the Standby circuitry.

### 3.1.5 Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique which consists in increasing or decreasing the voltage used for the digital peripherals ( $V_{CORE}$ ), according to the circumstances.

Dynamic voltage scaling to increase  $V_{CORE}$  is known as overvolting. It allows to improve the device performance. Refer to [Figure 3](#) for a description of the STM32L15xxx operating conditions versus performance.

Dynamic voltage scaling to decrease  $V_{CORE}$  is known as undervolting. It is performed to save power, particularly in laptops and other mobile devices where the energy comes from a battery and is thus limited.

#### Range 1

Range 1 is the “high performance” range.

The voltage regulator outputs a 1.8 V voltage (typical) as long as the  $V_{DD}$  input voltage is above 2.0 V. Flash program and erase operations can be performed in this range.

### Range 2 and 3

The regulator can also be programmed to output a regulated 1.5 V (typical, range 2) or a 1.2 V (typical, range 3) without any limitations on  $V_{DD}$  (1.65 to 3.6 V).

- At 1.5 V, the Flash memory is still functional but with medium read access time. This is the “medium performance” range. Program and erase operations on the Flash memory are still possible.
- At 1.2 V, the Flash memory is still functional but with slow read access time. This is the “low performance” range. Program and erase operations on the Flash memory are not possible under these conditions.

Refer to [Table 8](#) for details on the performance for each range.

**Table 8. Performance versus  $V_{CORE}$  ranges**

CPU performance	Power performance	$V_{CORE}$ range	Typical Value (V)	Max frequency (MHz)		$V_{DD}$ range
				1 WS	0 WS	
High	Low	1	1.8	32	16	2.0 - 3.6
Medium	Medium	2	1.5	16	8	1.65 - 3.6
Low	High	3	1.2	4	2	

Figure 3. STM32L15xxx performance versus V<sub>DD</sub> and V<sub>CORE</sub> range

### 3.1.6 Dynamic voltage scaling configuration

The following sequence is required to program the voltage regulator ranges:

1. Check V<sub>DD</sub> to identify which ranges are allowed (see [Figure 3: STM32L15xxx performance versus V<sub>DD</sub> and V<sub>CORE</sub> range](#)).
2. Poll VOSF bit of in PWR\_CSR. Wait until it is reset to 0.
3. Configure the voltage scaling range by setting the VOS[12:11] bits in the PWR\_CR register.
4. Poll VOSF bit of in PWR\_CSR register. Wait until it is reset to 0.

*Note:* During voltage scaling configuration, the system clock is stopped until the regulator is stabilized (VOSF=0). This must be taken into account during application development, in case a critical reaction time to interrupt is needed, and depending on peripheral used (timer, communication,...).

### 3.1.7 Voltage regulator and clock management when $V_{DD}$ drops below 2.0 V

When  $V_{CORE}$  range 1 is selected and  $V_{DD}$  drops below 2.0 V, the application must reconfigure the system.

A three-step sequence is required to reconfigure the system:

1. Detect that  $V_{DD}$  drops below 2.0 V:  
Use the PVD to monitor the  $V_{DD}$  voltage and to generate an interrupt when the voltage goes under the selected level. To detect the 2.0 V voltage limit, the application can select by software PVD threshold 2 (2.26 V typical). For more details on the PVD, refer to [Section 3.2.3](#).
2. Adapt the clock frequency to the voltage range that will be selected at next step:  
Below 2.0 V, the system clock frequency is limited to 16 MHz for range 2 and 4 MHz for range 3.
3. Select the required voltage range:  
Note that when  $V_{DD}$  is below 2.0 V, only range 2 or range 3 can be selected.

*Note:* When  $V_{CORE}$  range 2 or range 3 is selected and  $V_{DD}$  drops below 2.0 V, no system reconfiguration is required.

### 3.1.8 Voltage regulator and clock management when modifying the $V_{CORE}$ range

When  $V_{DD}$  is above 2.0 V, any of the 3 voltage ranges can be selected:

- When the voltage range is above the targeted voltage range (e.g. from range 1 to 2):
  - a) Adapt the clock frequency to the lower voltage range that will be selected at next step.
  - b) Select the required voltage range.
- When the voltage range is below the targeted voltage range (e.g. from range 3 to 1):
  - a) Select the required voltage range.
  - b) Tune the clock frequency if needed.

When  $V_{DD}$  is below 2.0 V, only range 2 and 3 can be selected:

- From range 2 to range 3
  - a) Adapt the clock frequency to voltage range 3.
  - b) Select voltage range 3.
- From range 3 to range 2
  - a) Select the voltage range 2.
  - b) Tune the clock frequency if needed.

## 3.2 Power supply supervisor

The device has an integrated zeropower power on reset (POR)/power down reset (PDR), coupled with a brown out reset (BOR) circuitry. For devices operating between 1.8 and 3.6 V, the BOR is always active at power-on and ensures proper operation starting from 1.8 V. After the 1.8 V BOR threshold is reached, the option byte loading process starts, either to confirm or modify default thresholds, or to disable BOR permanently (in which case, the  $V_{DD}$

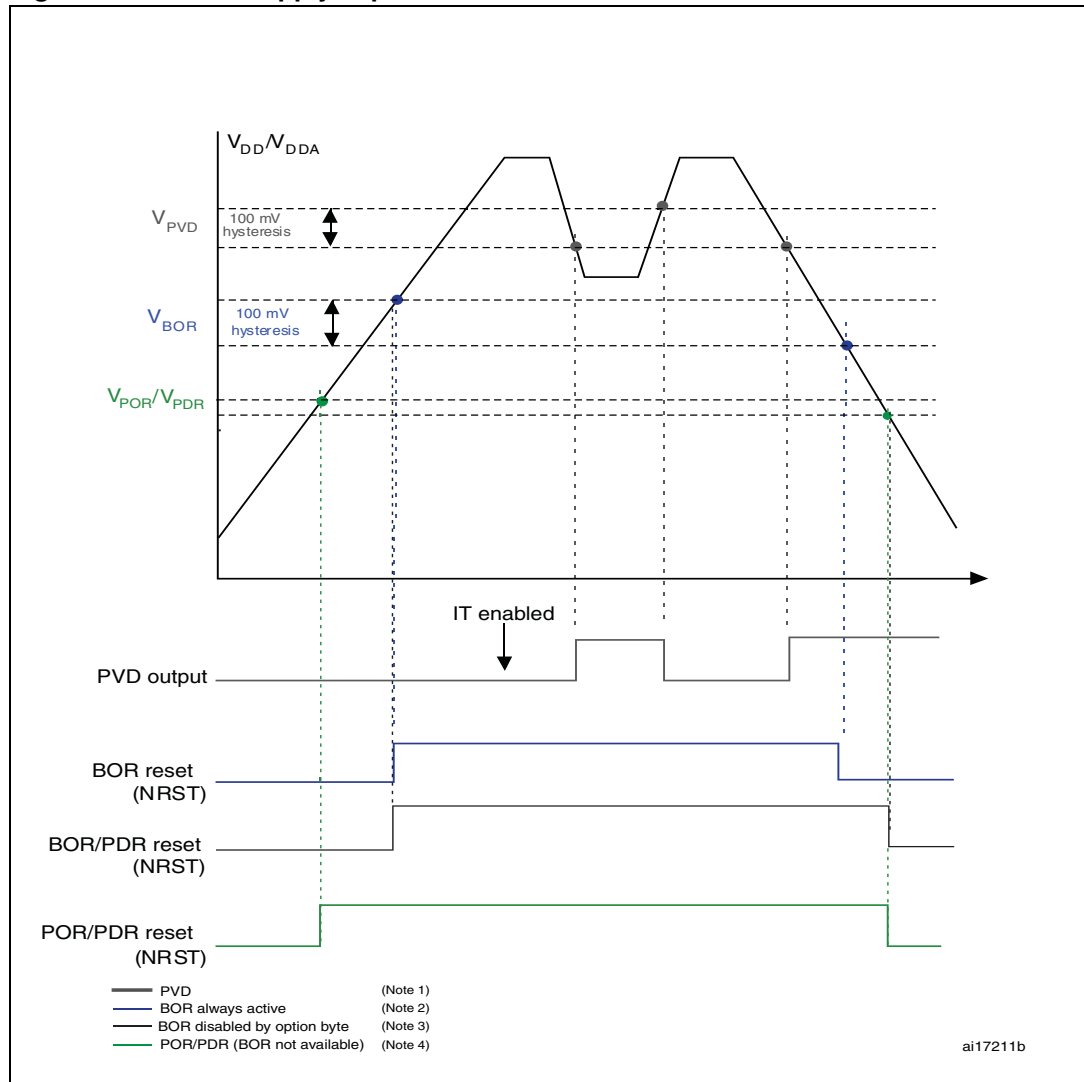

min value at power down is 1.65 V). For devices operating between 1.65 V and 3.6 V, the BOR is permanently disabled. Consequently, the start-up time at power-on can be decreased down to 1 ms typically.

Five BOR thresholds can be configured by option bytes, starting from 1.65 to 3 V. To reduce the power consumption in Stop mode, the internal voltage reference,  $V_{REFINT}$ , can be automatically switch off. The device remains in reset mode when  $V_{DD}$  is below a specified threshold,  $V_{POR}$ ,  $V_{PDR}$  or  $V_{BOR}$ , without the need for any external reset circuit.

The device features an embedded programmable voltage detector (PVD) that monitors the  $V_{DD}/V_{DDA}$  power supply and compares it to the  $V_{PVD}$  threshold. 7 different PVD levels can be selected by software between 1.85 and 3.05 V, with a 200 mV step. An interrupt can be generated when  $V_{DD}/V_{DDA}$  drops below the  $V_{PVD}$  threshold and/or when  $V_{DD}/V_{DDA}$  is higher than the  $V_{PVD}$  threshold. The interrupt service routine then generates a warning message and/or put the MCU into a safe state. The PVD is enabled by software.

The different power supply supervisor (POR, PDR, BOR, PVD) are illustrated in [Figure 4](#).

Figure 4. Power supply supervisors

1. The PVD is available on all STM32L devices and it is enabled or disabled by software.
2. The BOR is available only on devices operating from 1.8 to 3.6 V, and unless disabled by option byte it will mask the POR/PDR threshold.
3. When the BOR is disabled by option byte, the reset is asserted when  $V_{DD}$  goes below PDR level
4. For devices operating from 1.65 to 3.6 V, there is no BOR and the reset is released when  $V_{DD}$  goes above POR level and asserted when  $V_{DD}$  goes below PDR level

### 3.2.1 Power on reset (POR)/power down reset (PDR)

The device has an integrated POR/PDR circuitry that allows operation down to 1.5 V.

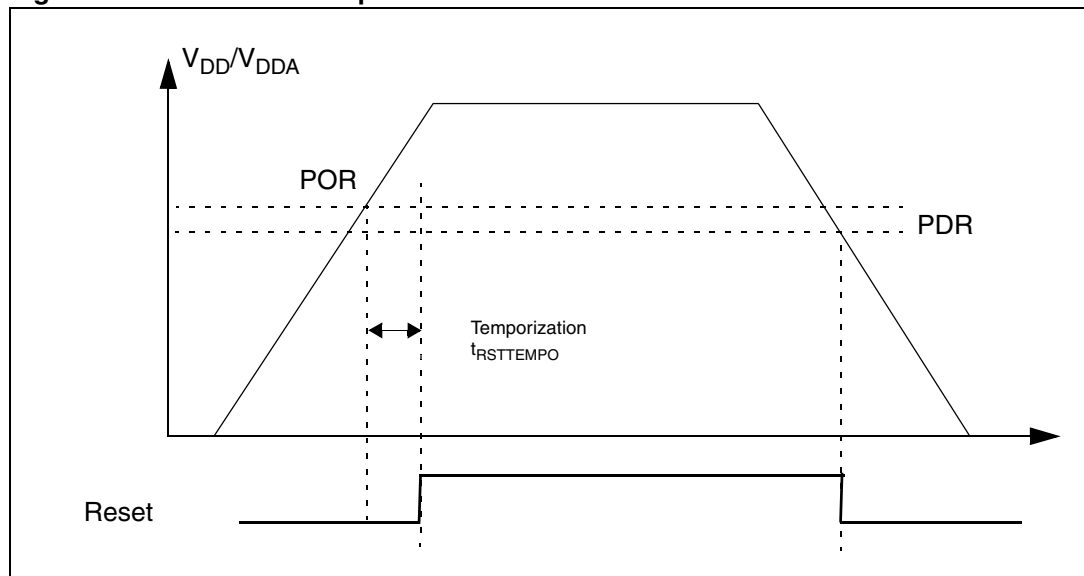

During power on, the device remains in Reset mode when  $V_{DD}/V_{DDA}$  is below a specified threshold,  $V_{POR}$ , without the need for an external reset circuit. The POR feature is always enabled and the POR threshold is 1.5 V.

During power down, the PDR keeps the device under reset when the supply voltage ( $V_{DD}$ ) drops below the  $V_{PDR}$  threshold. The PDR feature is always enabled and the PDR threshold is 1.5 V.

The POR and PDR are used only when the BOR is disabled (see [Section 3.2.2: Brown out reset \(BOR\)](#)). To insure the minimum operating voltage (1.65 V), the BOR should be configured to BOR Level 0. When the BOR is disabled, a “grey zone” exist between the minimum operating voltage (1.65 V) and the  $V_{POR}/V_{PDR}$  threshold. This means that  $V_{DD}$  can be lower than 1.65 V without device reset until the  $V_{PDR}$  threshold is reached.

For more details concerning the power on/power down reset threshold, refer to the electrical characteristics of the datasheet.

**Figure 5. Power on reset/power down reset waveform**

### 3.2.2 Brown out reset (BOR)

During power on, the Brown out reset (BOR) keeps the device under reset until the supply voltage reaches the specified  $V_{BOR}$  threshold.

For devices operating from 1.65 to 3.6 V, the BOR option is not available and the power supply is monitored by the POR/PDR. As the POR/PDR thresholds are at 1.5 V, a "grey

zone" exists between the  $V_{POR}/V_{PDR}$  thresholds and the minimum product operating voltage 1.65 V.

For devices operating from 1.8 to 3.6 V, the BOR is always active at power on and its threshold is 1.8 V.

Then when the system reset is released, the BOR level can be reconfigured or disabled by option byte loading.

If the BOR level is kept at the lowest level, 1.8 V at power on and 1.65 V at power down, the system reset is fully managed by the BOR and the product operating voltages are within safe ranges.

And when the BOR option is disabled by option byte, the power down reset is controlled by the PDR and a "grey zone" exists between the 1.65 V and  $V_{PDR}$ .

$V_{BOR}$  is configured through device option bytes. By default, the Level 4 threshold is activated. 5 programmable  $V_{BOR}$  thresholds can be selected.

- BOR Level 0 ( $V_{BOR0}$ ): reset threshold level for 1.69 to 1.80 V voltage range
- BOR Level 1 ( $V_{BOR1}$ ): reset threshold level for 1.94 to 2.1 V voltage range
- BOR Level 2 ( $V_{BOR2}$ ): reset threshold level for 2.3 to 2.49 V voltage range
- BOR Level 3 ( $V_{BOR3}$ ): reset threshold level for 2.54 to 2.74 V voltage range
- BOR Level 4 ( $V_{BOR4}$ ): reset threshold level for 2.77 to 3.0 V voltage range

When the supply voltage ( $V_{DD}$ ) drops below the selected  $V_{BOR}$  threshold, a device reset is generated. When the  $V_{DD}$  is above the  $V_{BOR}$  upper limit the device reset is released and the system can start.

BOR can be disabled by programming the device option bytes. To disable the BOR function,  $V_{DD}$  must have been higher than  $V_{BOR0}$  to start the device option byte programming sequence. The power on and power down is then monitored by the POR and PDR (see [Section 3.2.1: Power on reset \(POR\)/power down reset \(PDR\)](#))

The BOR threshold hysteresis is ~100 mV (between the rising and the falling edge of the supply voltage).

**Figure 6. BOR thresholds**

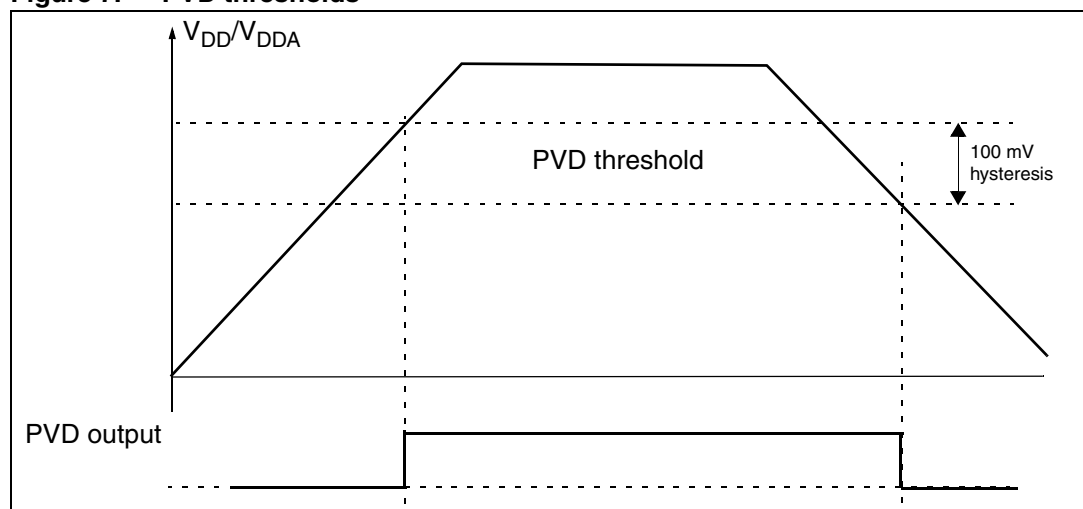

### 3.2.3 Programmable voltage detector (PVD)

You can use the PVD to monitor the  $V_{DD}/V_{DDA}$  power supply by comparing it to a threshold selected by the PLS[2:0] bits in the PWR\_CR (see [Section 3.4.1](#)).

The PVD can use an external input analog voltage (PVD\_IN) which is compared internally to VREFINT. The PVD\_IN (PB7) has to be configured in Analog mode when PLS[2:0] = 111. The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the PWR\_CSR (see [Section 3.4.2](#)), to indicate if  $V_{DD}/V_{DDA}$  is higher or lower than the PVD threshold. This event is internally connected to the EXTI line16 and can generate an interrupt if enabled through the EXTI registers. The PVD output interrupt can be generated when  $V_{DD}/V_{DDA}$  drops below the PVD threshold and/or when  $V_{DD}/V_{DDA}$  rises above the PVD threshold depending on EXTI line16 rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

**Figure 7. PVD thresholds**

### 3.2.4 Internal voltage reference ( $V_{REFINT}$ )

The functions managed through the internal voltage reference ( $V_{REFINT}$ ) are BOR, PVD, ADC, LCD and comparators. The internal voltage reference ( $V_{REFINT}$ ) is always enabled.

The internal voltage reference consumption is not negligible, in particular in Stop and Standby mode. To reduce power consumption, the ULP bit (Ultra low power) in the PWR\_CR register can be set to disable the internal voltage reference. However, in this case, when exiting from the Stop/Standby mode, the functions managed through the internal voltage reference are not reliable during the internal voltage reference startup time (up to 3 ms).

To reduce the wakeup time, the device can exit from Stop/Standby mode without waiting for the internal voltage reference startup time. This is performed by setting the FWU bit (Fast wakeup) in the PWR\_CR register before entering Stop/Standby mode.

If the ULP bit is set, the functions that were enabled before entering the Stop/Standby mode will be disabled during these modes, and enabled again only after the end of the internal voltage reference startup time whatever FWU value. The VREFINTRDYF flag in the PWR\_CSR register indicates that the internal voltage reference is ready.

### 3.3 Low-power modes

By default, the microcontroller is in Run mode after a system or a power on reset. In Run mode the CPU is clocked by HCLK and the program code is executed. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, performance, short startup time and available wakeup sources.

The devices feature five low-power modes:

- Low power run mode: regulator in low power mode, limited clock frequency, limited number of peripherals running
- Sleep mode: Cortex-M3 core stopped, peripherals kept running
- Low power sleep mode: Cortex-M3 core stopped, limited clock frequency, limited number of peripherals running, regulator in low power mode, RAM in power down, Flash stopped.
- Stop mode (all clocks are stopped, regulator running, regulator in low power mode)
- Standby mode:  $V_{CORE}$  domain powered off

In addition, the power consumption in Run mode can be reduce by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APBx and AHBx peripherals when they are unused.

**Table 9. Summary of low-power modes**

Mode name	Entry	Wakeup	Effect on $V_{CORE}$ domain clocks	Effect on $V_{DD}$ domain clocks	Voltage regulator
Low power run	LPSDSR and LPRUN bits + Clock setting	The regulator is forced in Main regulator (1.8 V)	None	None	In low power mode
Sleep (Sleep now or Sleep-on-exit)	WFI	Any interrupt	CPU CLK OFF no effect on other clocks or analog clock sources	None	ON
	WFE	Wakeup event			

**Table 9. Summary of low-power modes**

Mode name	Entry	Wakeup	Effect on V <sub>CORE</sub> domain clocks	Effect on V <sub>DD</sub> domain clocks	Voltage regulator
Low power sleep (Sleep now or Sleep-on-exit)	LPSDSR bits + WFI	Any interrupt	CPU CLK OFF no effect on other clocks or analog clock sources, Flash CLK OFF	None	In low power mode
	LPSDSR bits + WFE	Wakeup event			
Stop	PDDS, LPSDSR bits + SLEEPDEEP bit + WFI or WFE	Any EXTI line (configured in the EXTI registers, internal and external lines)	All V <sub>CORE</sub> domain clocks OFF	HSI and HSE and MSI oscillators OFF	ON, in low power mode (depending on PWR_CR)
Standby	PDDS bit + SLEEPDEEP bit + WFI or WFE	WKUP pin rising edge, RTC alarm (Alarm A or Alarm B), RTC Wakeup event, RTC tamper event, RTC timestamp event, external reset in NRST pin, IWDG reset			OFF

### 3.3.1 Behavior of clocks in low power modes

APB peripheral and DMA clocks can be disabled by software.

#### Sleep and Low power sleep modes

The CPU clock is stopped in Sleep and Low power sleep mode. The memory interface clocks (FLITF and RAM interfaces) and all peripherals clocks can be stopped by software during Sleep. The memory interface (FLITF) clock is stopped and the RAM is in power-down when in Low power sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep/Low power sleep mode when all the clocks of the peripherals connected to them are disabled.

#### Stop and Standby modes

The system clock and all high speed clocks are stopped in Stop and Standby modes:

- PLL is disabled
- Internal RC 16 MHz (HSI) oscillator is disabled
- External 1-24 MHz (HSE) oscillator is disabled
- Internal 65 kHz - 4 MHz (MSI) oscillator is disabled

When exiting this mode by interrupt (Stop mode) or by reset (Standby mode), the internal MSI oscillator is selected as system clock. When the device exits Stop mode, the previous MSI configuration (range and trimming value) is kept. When exiting Standby mode, the range and trimming value are reset to the default 2 MHz values.

If a Flash program operation or an access to APB domain is ongoing, the Stop/Standby mode entry is delayed until the Flash memory or the APB access has completed.

### 3.3.2 Slowing down system clocks

In Run mode the speed of the system clocks (SYSCLK, HCLK, PCLK1, PCLK2) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down peripherals before entering Sleep mode.

For more details refer to [Section 4.3.3: Clock configuration register \(RCC\\_CFGR\)](#).

### 3.3.3 Peripheral clock gating

In Run mode, the HCLK and PCLKx for individual peripherals and memories can be stopped at any time to reduce power consumption.

To further reduce power consumption in Sleep mode the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

Peripheral clock gating is controlled by the AHB peripheral clock enable register (RCC\_AHBENR), APB2 peripheral clock enable register (RCC\_APB2ENR), APB1 peripheral clock enable register (RCC\_APB1ENR) (see [Section 4.3.8: AHB peripheral clock enable register \(RCC\\_AHBENR\)](#), [Section 4.3.10: APB1 peripheral clock enable register \(RCC\\_APB1ENR\)](#) and [Section 4.3.9: APB2 peripheral clock enable register \(RCC\\_APB2ENR\)](#)).

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in RCC\_AHBLPENR and RCC\_APBxLPENR registers (x can 1 or 2).

### 3.3.4 Low power run mode (LP run)

To further reduce the consumption when the system is in Run mode, the regulator can be configured in low power mode. In this mode, the system frequency should not exceed 128 KHz.

Please refer to the product datasheet for more details on voltage regulator and peripherals operating conditions.

*Note:* To be able to read the RTC calendar register when the the APB1 clock frequency is less than seven times the RTC clock frequency ( $7 * RTCLCK$ ), the software must read the calendar time and date registers twice.

*If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done.*

Low power run mode can only be entered when  $V_{CORE}$  is in range 2. In addition, the dynamic voltage scaling must not be used when Low power run mode is selected. Only Stop and Sleep modes with regulator configured in Low power mode is allowed when Low power run mode is selected.

*Note:* In Low power run mode, all I/O pins keep the same state as in Run mode.

#### Entering Low power run mode

To enter Low power run mode proceed as follows:

- Each digital IP clock must be enabled or disabled by using the RCC\_APBxENR and RCC\_AHBENR registers.
- The frequency of the system clock must be decreased below 128 KHz.
- The regulator is forced in low power mode by software (LPRUN and LPSDSR bits set)

### Exiting Low power run mode

To exit Low power run mode proceed as follows:

- The regulator is forced in Main regulator mode by software.
- The Flash memory is switched on, if needed.
- The frequency of the clock system can be increased.

## 3.3.5 Sleep mode

### Entering Sleep mode

The Sleep mode is entered by executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions. Two options are available to select the Sleep mode entry mechanism, depending on the SLEEPONEXIT bit in the Cortex-M3 System Control register:

- Sleep-now: if the SLEEPONEXIT bit is cleared, the MCU enters Sleep mode as soon as WFI or WFE instruction is executed.
- Sleep-on-exit: if the SLEEPONEXIT bit is set, the MCU enters Sleep mode as soon as it exits the lowest priority ISR.

*Note:* In Sleep mode, all I/O pins keep the same state as in Run mode.

Refer to [Table 10: Sleep-now](#) and [Table 11: Sleep-on-exit](#) for details on how to enter Sleep mode.

### Exiting Sleep mode

If the WFI instruction is used to enter Sleep mode, any peripheral interrupt acknowledged by the nested vectored interrupt controller (NVIC) can wake up the device from Sleep mode.

If the WFE instruction is used to enter Sleep mode, the MCU exits Sleep mode as soon as an event occurs. The wakeup event can be generated either by:

- Enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex-M3 System Control register. When the MCU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
- Or configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

This mode offers the lowest wakeup time as no time is wasted in interrupt entry/exit.

Refer to [Table 10: Sleep-now](#) and [Table 11: Sleep-on-exit](#) for more details on how to exit Sleep mode.

**Table 10. Sleep-now**

Sleep-now mode	Description
<b>Mode entry</b>	WFI (Wait for Interrupt) or WFE (Wait for Event) while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 0 and</li> <li>– SLEEPONEXIT = 0</li> </ul> Refer to the Cortex™-M3 System Control register.
<b>Mode exit</b>	If WFI was used for entry: Interrupt: Refer to <a href="#">Table 28: Vector table</a> If WFE was used for entry: Wakeup event: Refer to <a href="#">Section 7.2.3: Wakeup event management</a>
<b>Wakeup latency</b>	None

**Table 11. Sleep-on-exit**

Sleep-on-exit	Description
<b>Mode entry</b>	WFI (wait for interrupt) while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 0 and</li> <li>– SLEEPONEXIT = 1</li> </ul> Refer to the Cortex™-M3 System Control register.
<b>Mode exit</b>	Interrupt: refer to <a href="#">Table 28: Vector table</a> .
<b>Wakeup latency</b>	None

### 3.3.6 Low power sleep mode (LP sleep)

#### Entering Low power sleep mode

The Low power sleep mode is entered by configuring the voltage regulator in low power mode, and by executing the WFI (wait for interrupt) or WFE (wait for event) instructions. In this mode, the Flash memory is not available but the RAM memory remains available.

In this mode, the system frequency should not exceed 128 KHz.

Please refer to product datasheet for more details on voltage regulator and peripherals operating conditions.

Low power sleep mode can only be entered when  $V_{CORE}$  is in range 2.

*Note:* To be able to read the RTC calendar register when the the APB1 clock frequency is less than seven times the RTC clock frequency ( $7 \cdot RTCLCK$ ), the software must read the calendar time and date registers twice.

*If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done.*

Two options are available to select the Sleep low power mode entry mechanism, depending on the SLEEPONEXIT bit in the Cortex-M3 System Control register:

- Sleep-now: if the SLEEPONEXIT bit is cleared, the MCU enters Sleep mode as soon as WFI or WFE instruction is executed.
- Sleep-on-exit: if the SLEEPONEXIT bit is set, the MCU enters Sleep mode as soon as it exits the lowest priority ISR.

To enter Low power sleep mode, proceed as follows:

- The Flash memory can be switched off by using the control bits (SLEEP\_PD in the FLASH\_ACR register. For more details refer to PM0062). This reduces power consumption but increases the wake-up time.
- Each digital IP clock must be enabled or disabled by using the RCC\_APBxENR and RCC\_AHBENR registers.
- The frequency of the system clock must be decreased.
- The regulator is forced in low power mode by software (LPSSDR bits set).
- A WFI/WFE instruction must be executed to enter in Sleep mode.

*Note:* In Low power sleep mode, all I/O pins keep the same state as in Run mode.

Refer to [Table 12: Sleep-now](#) and [Table 13: Sleep-on-exit](#) for details on how to enter Low power sleep mode.

### Exiting Low power sleep mode

If the WFI instruction was used to enter Low power sleep mode, any peripheral interrupt acknowledged by the nested vectored interrupt controller (NVIC) can wake up the device from Low power sleep mode.

If the WFE instruction was used to enter Low power sleep mode, the MCU exits Sleep mode as soon as an event occurs. The wakeup event can be generated:

- By enabling an interrupt in the peripheral control register but not in the NVIC, and by enabling the SEVONPEND bit in the Cortex-M3 System Control register. When the MCU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit in the NVIC interrupt clear pending register must be cleared.
- Or by configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

When exiting Low power sleep mode by issuing an interrupt or a wakeup event, the regulator is configured in Main regulator mode, the Flash memory is switched on (if necessary), and the system clock can be increased.

When the voltage regulator operates in low power mode, an additional startup delay is incurred when waking up from Low power sleep mode.

Refer to [Table 12: Sleep-now](#) and [Table 13: Sleep-on-exit](#) for more details on how to exit Sleep low power mode.

Table 12. Sleep-now

Sleep-now mode	Description
<b>Mode entry</b>	Voltage regulator in low power mode and the Flash memory switched off WFI (Wait for Interrupt) or WFE (wait for event) while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 0 and</li> <li>– SLEEPONEXIT = 0</li> </ul> Refer to the Cortex™-M3 System Control register.
<b>Mode exit</b>	Voltage regulator in Main regulator mode and the Flash memory switched on If WFI was used for entry: Interrupt: Refer to <a href="#">Table 28: Vector table</a> If WFE was used for entry: Wakeup event: Refer to <a href="#">Section 7.2.3: Wakeup event management</a>
<b>Wakeup latency</b>	Regulator wakeup time from low power mode

Sleep-on-exit	Description
<b>Mode entry</b>	Voltage regulator in low power mode and the Flash memory switched off WFI (wait for interrupt) while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 0 and</li> <li>– SLEEPONEXIT = 1</li> </ul> Refer to the Cortex™-M3 System Control register.
<b>Mode exit</b>	Interrupt: refer to <a href="#">Table 20: Vector table</a> .
<b>Wakeup latency</b>	regulator wakeup time from low power mode

### 3.3.7 Stop mode

The Stop mode is based on the Cortex-M3 deepsleep mode combined with peripheral clock gating. The voltage regulator can be configured either in normal or low-power mode. In Stop mode, all clocks in the V<sub>CORE</sub> domain are stopped, the PLL, the MSI, the HSI and the HSE RC oscillators are disabled. Internal SRAM and register contents are preserved.

To get the lowest consumption in Stop mode, the internal Flash memory also enters low power mode. When the Flash memory is in power down mode, an additional startup delay is incurred when waking up from Stop mode.

To minimize the consumption In Stop mode, V<sub>REFINT</sub>, the BOR, PVD, and temperature sensor can be switched off before entering the Stop mode. They can be switched on again by software after exiting the Stop mode using the ULP bit in the PWR\_CR register.

*Note:* In Stop mode, all I/O pins keep the same state as in Run mode.

#### Entering the Stop mode

Refer to [Table 14](#) for details on how to enter the Stop mode.

To further reduce power consumption in Stop mode, the internal voltage regulator can be put in low power mode. This is configured by the LPSSDR bit in the PWR\_CR register (see [Section 3.4.1](#)).

If Flash memory programming or an access to the APB domain is ongoing, the Stop mode entry is delayed until the memory or APB access has completed.

In Stop mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset. Refer to [Section 16.3](#) in [Section 16: Independent watchdog \(IWDG\)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the RCC\_CSR register (see [Section 4.3.14](#)).
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the RCC\_CSR register.
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the RCC\_CSR register.

The ADC, DAC or LCD can also consume power in Stop mode, unless they are disabled before entering it. To disable them, the ADON bit in the ADC\_CR2 register and the ENx bit in the DAC\_CR register must both be written to 0.

**Exiting the Stop mode**

Refer to [Table 14](#) for more details on how to exit Stop mode.

When exiting Stop mode by issuing an interrupt or a wakeup event, the MSI RC oscillator is selected as system clock.

When the voltage regulator operates in low power mode, an additional startup delay is incurred when waking up from Stop mode. By keeping the internal regulator ON during Stop mode, the consumption is higher although the startup time is reduced.

**Table 14. Stop mode**

Stop mode	Description
<b>Mode entry</b>	WFI (Wait for Interrupt) or WFE (Wait for Event) while: <ul style="list-style-type: none"> <li>– Set SLEEPDEEP bit in Cortex™-M3 System Control register</li> <li>– Clear PDDS bit in Power Control register (PWR_CR)</li> <li>– Select the voltage regulator mode by configuring LPSDSR bit in PWR_CR</li> </ul> <b>Note:</b> To enter the Stop mode, all EXTI Line pending bits (in <a href="#">EXTI pending register (EXTI_PR)</a> ), the RTC Alarm (Alarm A and Alarm B), RTC wakeup, RTC tamper, and RTC time-stamp flags, must be reset. Otherwise, the Stop mode entry procedure is ignored and program execution continues.
<b>Mode exit</b>	If WFI was used for entry: <ul style="list-style-type: none"> <li>Any EXTI Line configured in Interrupt mode (the corresponding EXTI Interrupt vector must be enabled in the NVIC). Refer to <a href="#">Table 20: Vector table on page 147</a>.</li> </ul> If WFE was used for entry: <ul style="list-style-type: none"> <li>Any EXTI Line configured in event mode. Refer to <a href="#">Section 8.2.3: Wakeup event management on page 152</a></li> </ul>
<b>Wakeup latency</b>	MSI RC wakeup time + regulator wakeup time from Low-power mode + FLASH wakeup time

### 3.3.8 Standby mode

The Standby mode allows to achieve the lowest power consumption. It is based on the Cortex-M3 deepsleep mode, with the voltage regulator disabled. The  $V_{CORE}$  domain is consequently powered off. The PLL, the MSI, the HSI oscillator and the HSE oscillator are also switched off. SRAM and register contents are lost except for the RTC registers, RTC backup registers and Standby circuitry (see [Figure 2](#)).

#### Entering the Standby mode

Refer to [Table 15](#) for more details on how to enter Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset. Refer to [Section 16.3](#) in [Section 16: Independent watchdog \(IWDG\)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the RCC\_CSR register (see [Section 4.3.14](#)).
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the RCC\_CSR register.
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the RCC\_CSR register.

#### Exiting the Standby mode

The microcontroller exits Standby mode when an external Reset (NRST pin), an IWDG Reset, a rising edge on WKUP pins (WKUP1, WKUP2 or WKUP3), an RTC alarm, a tamper event, or a time-stamp event is detected. All registers are reset after wakeup from Standby except for [PWR power control/status register \(PWR\\_CSR\)](#).

After waking up from Standby mode, program execution restarts in the same way as after a Reset (boot pins sampling, vector reset is fetched, etc.). The SBF status flag in the PWR\_CSR register (see [Section 3.4.2](#)) indicates that the MCU was in Standby mode.

Refer to [Table 15](#) for more details on how to exit Standby mode.

**Table 15. Standby mode**

Standby mode	Description
<b>Mode entry</b>	WFI (Wait for Interrupt) or WFE (Wait for Event) while: <ul style="list-style-type: none"> <li>– Set SLEEPDEEP in Cortex™-M3 System Control register</li> <li>– Set PDDS bit in Power Control register (PWR_CR)</li> <li>– Clear WUF bit in Power Control/Status register (PWR_CSR)</li> <li>– Clear the RTC flag corresponding to the chosen wakeup source (RTC Alarm A, RTC Alarm B, RTC wakeup, Tamper or Time-stamp flags)</li> </ul>
<b>Mode exit</b>	WKUP pin rising edge, RTC alarm (Alarm A and Alarm B), RTC wakeup, tamper event, time-stamp event, external reset in NRST pin, IWDG reset.
<b>Wakeup latency</b>	Reset phase

### I/O states in Standby mode

In Standby mode, all I/O pins are high impedance except for:

- Reset pad (still available)
- RTC\_AF1 pin (PC13) if configured for Wakeup pin 2 (WKUP2), tamper, time-stamp, RTC Alarm out, or RTC clock calibration out.
- WKUP pin 1 (PA0) and WKUP pin 3 (PE6), if enabled.

### Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while the debug features are used. This is due to the fact that the Cortex™-M3 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU\_CR register, the software can be debugged even when using the low-power modes extensively. For more details, refer to [Section 24.16.1: Debug support for low-power modes](#).

## 3.3.9 Waking up the device from Stop and Standby modes using the RTC and comparators

The MCU can be woken up from low-power mode by an RTC Alarm event, an RTC Wakeup event, a tamper event, a time-stamp event, or a comparator event, without depending on an external interrupt (Auto-wakeup mode).

These RTC alternate functions can wake up the system from Stop and Standby low power modes while the comparator events can only wake up the system from Stop mode.

The system can also wake up from low power modes without depending on an external interrupt (Auto-wakeup mode) by using the RTC alarm or the RTC wakeup events.

The RTC provides a programmable time base for waking up from Stop or Standby mode at regular intervals. For this purpose, two of the three alternative RTC clock sources can be selected by programming the RTCSEL[1:0] bits in the RCC\_CSR register (see [Section 4.3.14](#)):

- Low-power 32.768 kHz external crystal oscillator (LSE OSC).  
This clock source provides a precise time base with very low-power consumption (less than 1  $\mu$ A added consumption in typical conditions)
- Low-power internal RC oscillator (LSI RC)  
This clock source has the advantage of saving the cost of the 32.768 kHz crystal. This internal RC Oscillator is designed to use minimum power consumption.

### RTC auto-wakeup (AWU) from the Stop mode

- To wake up from the Stop mode with an RTC alarm event, it is necessary to:
  - a) Configure the EXTI Line 17 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC Alarm interrupt in the RTC\_CR register
  - c) Configure the RTC to generate the RTC alarm
- To wake up from the Stop mode with an RTC Tamper or time stamp event, it is necessary to:
  - a) Configure the EXTI Line 19 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC TimeStamp Interrupt in the RTC\_CR register or the RTC Tamper Interrupt in the RTC\_TCR register
  - c) Configure the RTC to detect the tamper or time stamp event
- To wake up from the Stop mode with an RTC Wakeup event, it is necessary to:
  - a) Configure the EXTI Line 20 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC Wakeup Interrupt in the RTC\_CR register
  - c) Configure the RTC to generate the RTC Wakeup event

### RTC auto-wakeup (AWU) from the Standby mode

- To wake up from the Standby mode with an RTC alarm event, it is necessary to:
  - a) Enable the RTC Alarm interrupt in the RTC\_CR register
  - b) Configure the RTC to generate the RTC alarm
- To wake up from the Stop mode with an RTC Tamper or time stamp event, it is necessary to:
  - a) Enable the RTC TimeStamp Interrupt in the RTC\_CR register or the RTC Tamper Interrupt in the RTC\_TCR register
  - b) Configure the RTC to detect the tamper or time stamp event
- To wake up from the Stop mode with an RTC Wakeup event, it is necessary to:
  - a) Enable the RTC Wakeup Interrupt in the RTC\_CR register
  - b) Configure the RTC to generate the RTC Wakeup event

### Comparator auto-wakeup (AWU) from the Stop mode

- To wake up from the Stop mode with a comparator 1 or comparator 2 wakeup event, it is necessary to:
  - a) Configure the EXTI Line 21 for comparator 1 or EXTI Line 22 for comparator 2 (Interrupt or Event mode) to be sensitive to the selected edges (falling, rising or falling and rising)
  - b) Configure the comparator to generate the event

## 3.4 Power control registers

The peripheral registers have to be accessed by half-words (16-bit) or words (32-bit).

### 3.4.1 PWR power control register (PWR\_CR)

Address offset: 0x00

Reset value: 0x0000 1000 (reset by wakeup from Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	LPRUN	Res.	VOS[1:0]		FWU	ULP	DBP	PLS[2:0]			PVDE	CSBF	CWUF	PDDS	LPSDSR
	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rc_w1	rc_w1	rw	rw

Bits 31:15 Reserved, always read as 0.

Bit 14 **LPRUN**: Low power run mode

When LPRUN bit is set together with the LPSDSR bit, the regulator is switched from main mode to low power mode. Otherwise, it remains in main mode. The regulator goes back to operate in main mode when LPRUN is reset.

It is forbidden to reset LPSDSR when the MCU is in Low power run mode mode. LPSDSR is used as a prepositioning for the entry into low power mode, indicating to the system which configuration of the regulator will be selected when entering Low power mode. The LPSDSR bit must be set before the LPRUN bit is set. LPSDSR can be reset only when LPRUN bit=0.

- 0: Voltage regulator in main mode in Low power run mode
- 1: Voltage regulator in low power mode in Low power run mode

Bits 13 Reserved, always read as 0.

Bits 12:11 **VOS[1:0]**: Voltage scaling range selection

These bits are used to select the internal regulator voltage range.

Before resetting the power interface by resetting the PWRRST bit in the RCC\_APB1RSTR register, these bits have to be set to "10" and the frequency of the system has to be configured accordingly.

- 00: forbidden (range1 will be automatically selected)
- 01: 1.8 V (range 1)
- 10: 1.5 V (range 2)
- 11: 1.2 V (range 3)

Bit 10 **FWU**: Fast wakeup

This bit works in conjunction with ULP bit.

If ULP = 0, FWU is ignored

If ULP = 1 and FWU = 1: V<sub>REFINT</sub> startup time is ignored when exiting from low power mode. The VREFINTRDYF flag in the PWR\_CSR register indicates when the V<sub>REFINT</sub> is ready again.

If ULP=1 and FWU = 0: Exiting from low power mode occurs only when the V<sub>REFINT</sub> is ready (after its startup time). This bit is not reset by resetting the PWRRST bit in the RCC\_APB1RSTR register.

- 0: Low power modes exit occurs only when V<sub>REFINT</sub> is ready
- 1: V<sub>REFINT</sub> start up time is ignored when exiting low power modes

Bit 9 **ULP**: Ultralow power mode

When set, the V<sub>REFINT</sub> is switched off in low power mode. This bit is not reset by resetting the PWRRST bit in the RCC\_APB1RSTR register.

- 0: V<sub>REFINT</sub> is on in low power mode
- 1: V<sub>REFINT</sub> is off in low power mode

Bit 8 **DBP**: Disable backup write protection

In reset state, the RTC, RTC backup registers and RCC CSR register are protected against parasitic write access. This bit must be set to enable write access to these registers.

- 0: Access to RTC, RTC Backup and RCC CSR registers disabled
- 1: Access to RTC, RTC Backup and RCC CSR registers enabled

*Note: If the HSE divided by 2, 4, 8 or 16 is used as the RTC clock, this bit must remain set to 1.*

Bits 7:5 **PLS[2:0]**: PVD level selection

These bits are written by software to select the voltage threshold detected by the power voltage detector:

- 000: 1.9 V
- 001: 2.1 V
- 010: 2.3 V
- 011: 2.5 V
- 100: 2.7 V
- 101: 2.9 V
- 110: 3.1 V

111: External input analog voltage (Compare internally to  $V_{REFINT}$ )

PVD\_IN input (PB7) has to be configured as analog input when PLS[2:0] = 111.

*Note: Refer to the electrical characteristics of the datasheet for more details.*

Bit 4 **PVDE**: Power voltage detector enable

This bit is set and cleared by software.

- 0: PVD disabled
- 1: PVD enabled

Bit 3 **CSBF**: Clear standby flag

This bit is always read as 0.

- 0: No effect
- 1: Clear the SBF Standby flag (write).

Bit 2 **CWUF**: Clear wakeup flag

This bit is always read as 0.

- 0: No effect
- 1: Clear the WUF Wakeup flag after 2 system clock cycles

Bit 1 **PDDS**: Power down deepsleep

This bit is set and cleared by software.

- 0: Enter Stop mode when the CPU enters deepsleep. The regulator is in low-power mode.
- 1: Enter Standby mode when the CPU enters deepsleep.

Bit 0 **LPSDSR**: Low-power deepsleep/sleep/low power run

– DeepSleep/Sleep modes

When this bit is set, the regulator switches in low power mode when the CPU enters sleep or deepsleep mode. The regulator goes back to main mode when the CPU exits from these modes.

– Low power run mode

When this bit is set, the regulator switches in low power mode when the bit LPRUN is set. The regulator goes back to main mode when the bit LPRUN is reset.

This bit is set and cleared by software.

- 0: Voltage regulator on during deepsleep/Sleep/Low power run mode
- 1: Voltage regulator in low power mode during deepsleep/Sleep/Low power run mode

### 3.4.2 PWR power control/status register (PWR\_CSR)

Address offset: 0x04

Reset value: 0x0000 0008 (not reset by wakeup from Standby mode)

Additional APB cycles are needed to read this register versus a standard APB read.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16			
Reserved																		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
Reserved				EWUP 3			EWUP 2		EWUP 1	Reserved			REG LPF	VOSF	VREFIN TRDYF	PVDO	SBF	WUF
				rw			rw		rw				r	r	r	r	r	r

Bits 31:11 Reserved, always read as 0.

Bit 10 **EWUP3**: Enable WKUP pin 3

This bit is set and cleared by software.

0: WKUP pin 3 is used for general purpose I/Os. An event on the WKUP pin 3 does not wakeup the device from Standby mode.

1: WKUP pin 3 is used for wakeup from Standby mode and forced in input pull down configuration (rising edge on WKUP pin 3 wakes-up the system from Standby mode).

*Note: This bit is reset by a system reset.*

Bit 9 **EWUP2**: Enable WKUP pin 2

This bit is set and cleared by software.

0: WKUP pin 2 is used for general purpose I/Os. An event on the WKUP pin 2 does not wakeup the device from Standby mode.

1: WKUP pin 2 is used for wakeup from Standby mode and forced in input pull down configuration (rising edge on WKUP pin 2 wakes-up the system from Standby mode).

*Note: This bit is reset by a system reset.*

Bit 8 **EWUP1**: Enable WKUP pin 1

This bit is set and cleared by software.

0: WKUP pin 1 is used for general purpose I/Os. An event on the WKUP pin 1 does not wakeup the device from Standby mode.

1: WKUP pin 1 is used for wakeup from Standby mode and forced in input pull down configuration (rising edge on WKUP pin 1 wakes-up the system from Standby mode).

*Note: This bit is reset by a system reset.*

Bits 7:6 Reserved, always read as 0.

Bit 5 **REGLPF** : Regulator LP flag

This bit is set by hardware when the MCU is in Low power run mode.

When the MCU exits from Low power run mode, this bit stays at 1 until the regulator is ready in main mode. A polling on this bit is recommended to wait for the regulator main mode. This bit is reset by hardware when the regulator is ready.

0: Regulator is ready in main mode

1: Regulator voltage is in low power mode

- Bit 4 **VOSF**: Voltage Scaling select flag  
 A delay is required for the internal regulator to be ready after the voltage range is changed. The VOSF bit indicates that the regulator has reached the voltage level defined with bits VOS of PWR\_CR register.  
 This bit is reset when VOS[1:0] in PWR\_CR register change. It is set once the regulator is ready.  
 0: Regulator is ready in the selected voltage range  
 1: Regulator voltage output is changing to the required VOS level.
- Bit 3 **VREFINTRDYF**: Internal voltage reference ( $V_{REFINT}$ ) ready flag  
 This bit indicates the state of the internal voltage reference,  $V_{REFINT}$ .  
 0:  $V_{REFINT}$  is OFF  
 1:  $V_{REFINT}$  is ready
- Bit 2 **PVDO**: PVD output  
 This bit is set and cleared by hardware. It is valid only if PVD is enabled by the PVDE bit.  
 0:  $V_{DD}/V_{DDA}$  is higher than the PVD threshold selected with the PLS[2:0] bits.  
 1:  $V_{DD}/V_{DDA}$  is lower than the PVD threshold selected with the PLS[2:0] bits.  
*Note: The PVD is stopped by Standby mode. For this reason, this bit is equal to 0 after Standby or reset until the PVDE bit is set.*
- Bit 1 **SBF**: Standby flag  
 This bit is set by hardware and cleared only by a POR/PDR (power on reset/power down reset) or by setting the CSBF bit in the [PWR power control register \(PWR\\_CR\)](#)  
 0: Device has not been in Standby mode  
 1: Device has been in Standby mode
- Bit 0 **WUF**: Wakeup flag  
 This bit is set by hardware and cleared only by a POR/PDR (power on reset/power down reset) or by setting the CWUF bit in the [PWR power control register \(PWR\\_CR\)](#)  
 0: No wakeup event occurred  
 1: A wakeup event was received from the WKUP pin or from the RTC alarm (Alarm A or Alarm B), RTC Tamper event, RTC TimeStamp event or RTC Wakeup).  
*Note: An additional wakeup event is detected if the WKUP pins are enabled (by setting the EWUPx (x=1, 2, 3) bits) when the WKUP pin levels are already high.*

### 3.4.3 PWR register map

The following table summarizes the PWR registers.

**Table 16. PWR - register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
0x000	PWR_CR	Reserved																		LPRUN	Reserved	VOS [1:0]		FWU	ULP	DBP	PLS[2:0]			PVDE	CSBF	CWUF	PDDS	LPSSR
	Reset value																			0	Reserved	1	0	0	0	0	0			0	0	0	0	0
0x004	PWR_CSR	Reserved																		EWUP3			EWUP2	EWUP1	Reserved	REGLPF	VOSF	VREFINTRDYF	PVDO	SBF	WUF			
	Reset value																			0			0	0	0	0	0	0	0	0	0	0		

Refer to [Table 1: Register boundary addresses](#) for the register boundary addresses.

## 4 Reset and clock control (RCC)

### 4.1 Reset

There are three types of reset, defined as system reset, power reset and RTC domain reset.

#### 4.1.1 System reset

A system reset sets all registers to their reset values except for the RTC, RTC backup registers and control/status register, RCC\_CSR.

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog end-of-count condition (WWDG reset)
3. Independent watchdog end-of-count condition (IWDG reset)
4. A software reset (SW reset) (see [Software reset](#))
5. Low-power management reset (see [Low-power management reset](#))
6. Option byte loader reset (see [Option byte loader reset](#))
7. Exit from Standby mode

The reset source can be identified by checking the reset flags in the control/status register, RCC\_CSR (see [Section 4.3.14](#)).

#### Software reset

The SYSRESETREQ bit in Cortex™-M3 Application Interrupt and Reset Control Register must be set to force a software reset on the device. Refer to the Cortex™-M3 technical reference manual for more details.

#### Low-power management reset

There are two ways to generate a low-power management reset:

1. Reset generated when entering Standby mode:  
This type of reset is enabled by resetting nRST\_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
2. Reset when entering Stop mode:  
This type of reset is enabled by resetting nRST\_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

#### Option byte loader reset

The Option byte loader reset is generated when the OBL\_LAUNCH bit (bit 18) is set in the FLASH\_PECR register. This bit is used to launch by software the option byte loading.

For further information on the user option bytes, refer to the STM32L15xxx Flash programming manual (PM0062).

### 4.1.2 Power reset

A power reset is generated when one of the following events occurs:

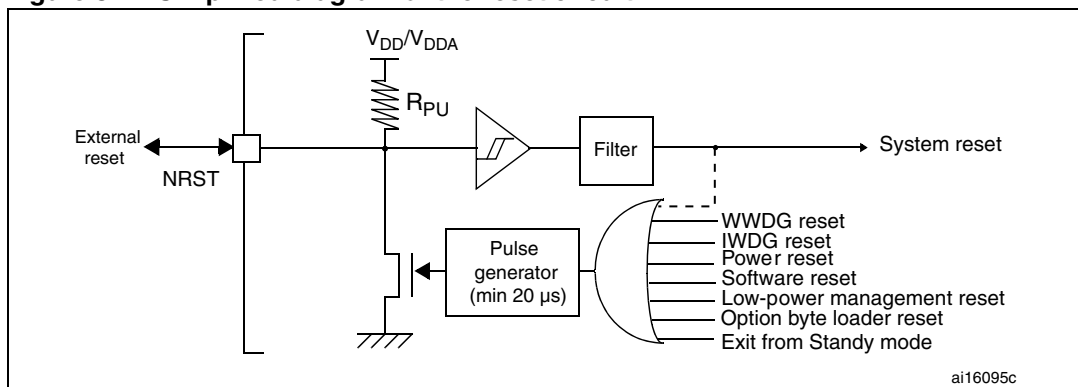

1. Power-on/power-down reset (POR/PDR reset)
2. BOR reset

A power reset sets all registers to their reset values including for the RTC domain (see [Figure 8](#))

These sources act on the NRST pin and it is always kept low during the delay phase. The RESET service routine vector is fixed at address 0x0000\_0004 in the memory map. For more details, refer to [Table 28: Vector table](#).

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20  $\mu\text{s}$  for each reset source (external or internal reset). In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

**Figure 8. Simplified diagram of the reset circuit**

### 4.1.3 RTC and backup registers reset

The RTC peripheral, RTC clock source selection (in RCC\_CSR) and the backup registers are reset only when one of the following events occurs:

1. A software reset, triggered by setting the RTCRST bit in the RCC\_CSR register (see [Section 4.3.14](#))
2. Power reset (BOR/POR/PDR)

## 4.2 Clocks

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI ((high-speed internal) oscillator clock
- HSE (high-speed external) oscillator clock
- PLL clock
- MSI (multispeed internal) oscillator clock

The MSI is used as system clock source after startup from Reset, wake-up from Stop or Standby low power modes.

The devices have the following two secondary clock sources:

- 37 kHz low speed internal RC (LSI RC) which drives the independent watchdog and optionally the RTC used for Auto-wakeup from Stop/Standby mode.
- 32.768 kHz low speed external crystal (LSE crystal) which optionally drives the real-time clock (RTCCLK)

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers allow the configuration of the AHB frequency, the high speed APB (APB2) and the low speed APB (APB1) domains. The maximum frequency of the AHB, APB1 and the APB2 domains is 32 MHz. It may depend on the device voltage range, for more details please refer to the Dynamic voltage scaling management section in the PWR chapter.

All the peripheral clocks are derived from the system clock (SYSCLK) except:

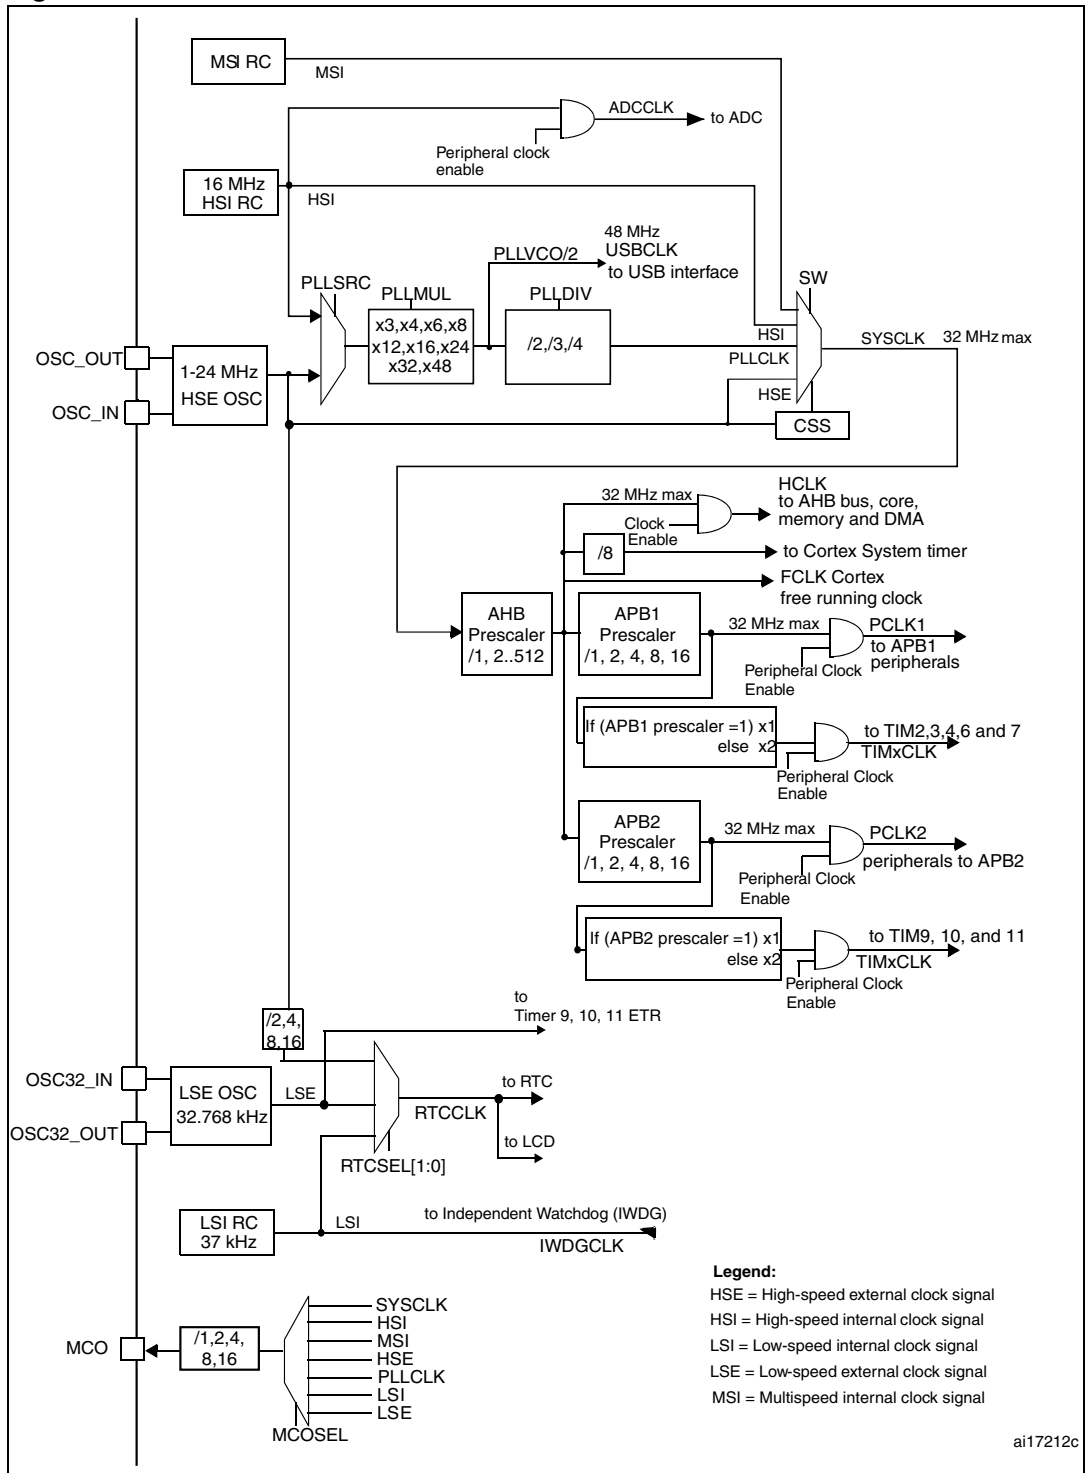

- The USB 48 MHz clock which is derived from the PLL VCO clock.
- The ADC clock which is always the HSI clock. A divider by 1, 2 or 4 allows to adapt the clock frequency to the device operating conditions. For more details please refer to the Operating Power Supply Range section in the PWR chapter.
- The RTC/LCD clock which is derived from the LSE, LSI or 1 MHz HSE\_RTC (HSE divided by a programmable prescaler).
- IWDG clock which is always the LSI clock.

The system clock (SYSCLK) frequency must be higher or equal to the RTC/LCD clock frequency.

The RCC feeds the Cortex System Timer (SysTick) external clock with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or with the Cortex clock (HCLK), configurable in the SysTick Control and Status Register.

Figure 9. Clock tree

1. For full details about the internal and external clock source characteristics, please refer to the “Electrical characteristics” section in your device datasheet.

The timer clock frequencies are automatically fixed by hardware. There are two cases:

1. If the APB prescaler is 1, the timer clock frequencies are set to the same frequency as that of the APB domain to which the timers are connected.
2. Otherwise, they are set to twice (×2) the frequency of the APB domain to which the timers are connected.

FCLK acts as Cortex™-M3 free running clock. For more details refer to the ARM Cortex™-M3 Technical Reference Manual.

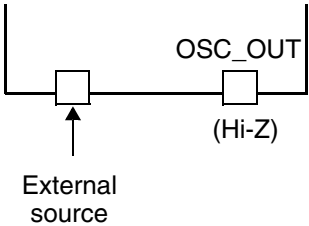

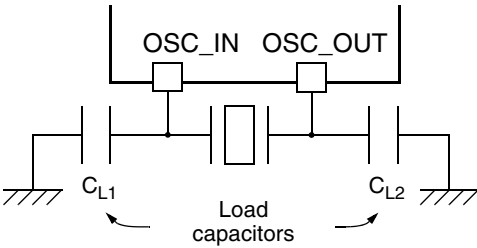

### 4.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

**Figure 10. HSE/ LSE clock sources**

Clock source	Hardware configuration
External clock	
Crystal/Ceramic resonators	

#### External source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 32 MHz. This mode is selected by setting the HSEBYP and HSEON bits in the Clock control register, RCC\_CR (see [Section 4.3.1](#)). The external clock signal (square, sinus or triangle)

with ~50% duty cycle has to drive the OSC\_IN pin while the OSC\_OUT pin should be left hi-Z (see [Figure 10](#)).

### External crystal/ceramic resonator (HSE crystal)

The 1 to 24 MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in [Figure 10](#). Refer to the electrical characteristics section of the *datasheet* for more details.

The HSERDY flag of the RCC\_CR register (see [Section 4.3.1](#)) indicates whether the HSE oscillator is stable or not. At startup, the HSE clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the RCC\_CR register.

The HSE Crystal can be switched on and off using the HSEON bit in the RCC\_CR register.

## 4.2.2 HSI clock

The HSI clock signal is generated from an internal 16 MHz RC oscillator. It can be used directly as a system clock or as PLL input.

The HSI RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

### Calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at an ambient temperature,  $T_A$ , of 25 °C.

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the Internal Clock Sources Calibration Register (RCC\_ICSCR) (see [Section 4.3.2](#)).

If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. You can trim the HSI frequency in the application by using the HSITRIM[4:0] bits in the RCC\_ICSCR register. For more details on how to measure the HSI frequency variation please refer to [Section 4.2.13: Internal/external clock measurement with TIM9/TIM10/TIM11](#).

The HSIRDY flag in the RCC\_CR indicates whether the HSI oscillator is stable or not. At startup, the HSI RC output clock is not released until this bit is set by hardware.

The HSI RC oscillator can be switched on and off using the HSION bit in the RCC\_CR register.

The HSI signal can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to [Section 4.2.9: Clock security system \(CSS\) on page 78](#).

## 4.2.3 MSI clock

The MSI clock signal is generated from an internal RC oscillator. Its frequency range can be adjusted by software by using the MSIRANGE[2:0] bits in the RCC\_ICSCR register (see [Section 4.3.2: Internal clock sources calibration register \(RCC\\_ICSCR\)](#)). Seven frequency ranges are available: 65.536 kHz, 131.072 kHz, 262.144 kHz, 524.288 kHz, 1.048 MHz, 2.097 MHz (default value) and 4.194 MHz.

The MSI clock is used as system clock after restart from Reset, wake-up from Stop, and Standby low power mode. After restart from Reset or wake-up from Standby, the MSI frequency is set to its default value. The MSI frequency does not change after waking up from Stop.

The MSI RC oscillator has the advantage of providing a low-cost (no external components) low-power clock source. It is used as wake-up clock in low power modes to reduce power consumption and wake-up time.

The MSIRDY flag in the RCC\_CR register indicates whether the MSI RC is stable or not. At startup, the MSI RC output clock is not released until this bit is set by hardware.

The MSI RC can be switched on and off by using the MSION bit in the RCC\_CR register (see [Section 4.3.1](#)).

It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to [Section 4.2.9: Clock security system \(CSS\) on page 78](#).

### Calibration

The MSI RC oscillator frequency can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at an ambient temperature,  $T_A$ , of 25 °C.

After reset, the factory calibration value is loaded in the MSICAL[7:0] bits in the RCC\_ICSCR register. If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. You can trim the MSI frequency in the application by using the MSITRIM[7:0] bits in the RCC\_ICSCR register. For more details on how to measure the MSI frequency variation please refer to [Section 4.2.13: Internal/external clock measurement with TIM9/TIM10/TIM11](#).

## 4.2.4 PLL

The internal PLL can be clocked by the HSI RC or HSE crystal. It is used to drive the system clock and to generate the 48 MHz clock for the USB peripheral (refer to [Figure 9](#) and [Section 4.3.1: Clock control register \(RCC\\_CR\)](#)).

The PLL input clock frequency must be between 2 and 24 MHz.

The desired frequency is obtained by using the multiplication factor and output division embedded in the PLL:

- If the USB interface is used in the application, the PLL VCO clock (defined by the PLL multiplication factor) must be programmed to output a 96 MHz frequency. This is required to provide a 48 MHz clock to the USB ( $USBCLK = PLLVCO/2$ ).
- The system clock is derived from the PLL VCO divided by the output division factor.

- Note:*
- 1 *The application software must set correctly the PLL multiplication factor to avoid exceeding 96 MHz as PLLVCO when the product is in range 1, 48 MHz as PLLVCO when the product is in range 2, 24 MHz when the product is in range 3. It must also set correctly the output division to avoid exceeding 32 MHz as SYSCLK.*
  - 2 *The minimum input clock frequency for PLL is 2 MHz (when using HSE as PLL source).*

The PLL configuration (selection of the source clock, multiplication factor and output division factor) must be performed before enabling the PLL. Once the PLL is enabled, these parameters cannot be changed.

To modify the PLL configuration, proceed as follows:

1. Disable the PLL by setting PLLON to 0.
2. Wait until PLLRDY is cleared. PLLRDY. The PLL is now fully stopped.
3. Change the desired parameter.
4. Enable the PLL again by setting PLLON to 1.

An interrupt can be generated when the PLL is ready if enabled in the RCC\_CIR register (see [Section 4.3.4](#)).

#### 4.2.5 LSE clock

The LSE crystal is a 32.768 kHz low speed external crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in the RCC\_CSR register (see [Section 4.3.14](#)).

The LSERDY flag in the RCC\_CSR register indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the RCC\_CIR register (see [Section 4.3.4](#)).

#### External source (LSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 1 MHz. This mode is selected by setting the LSEBYP and LSEON bits in the RCC\_CR (see [Section 4.3.1](#)). The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC32\_IN pin while the OSC32\_OUT pin should be left Hi-Z (see [Figure 10](#)).

#### 4.2.6 LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG). The clock frequency is around 37 kHz.

The LSI RC oscillator can be switched on and off using the LSION bit in the RCC\_CSR register (see [Section 4.3.14](#)).

The LSIRDY flag in RCC\_CSR indicates whether the low-speed internal oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the RCC\_CIR (see [Section 4.3.4](#)).

#### LSI measurement

The frequency dispersion of the LSI oscillator can be measured to have accurate RTC time base and/or IWDG timeout (when LSI is used as clock source for these peripherals) with an acceptable accuracy. For more details, refer to the electrical characteristics section of the datasheets. For more details on how to measure the LSI frequency, please refer to [Section 4.2.13: Internal/external clock measurement with TIM9/TIM10/TIM11](#).

### 4.2.7 System clock (SYSCLK) selection

Four different clock sources can be used to drive the system clock (SYSCLK):

- The HSI oscillator
- The HSE oscillator
- The PLL
- The MSI oscillator clock (default after reset)

When a clock source is used directly or through the PLL as system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source which is not yet ready is selected, the switch will occur when the clock source will be ready. Status bits in the RCC\_CR register indicate which clock(s) is (are) ready and which clock is currently used as system clock.

### 4.2.8 System clock source frequency versus voltage range

The following table gives the different clock source frequencies depending on the product voltage range.

**Figure 11. System clock source frequency**

Product voltage range	Clock frequency			
	MSI	HSI	HSE	PLL
Range 1 (1.8 V)	4 MHz	16 MHz	HSE 32 MHz (external clock) or 24 MHz (crystal)	32 MHz (PLLVCO max = 96 MHz)
Range 2 (1.5 V)	4 MHz	16 MHz	16 MHz	16 MHz (PLLVCO max = 48 MHz)
Range 3 (1.2 V)	4 MHz	NA	4 MHz	4 MHz (PLLVCO max = 24 MHz)

### 4.2.9 Clock security system (CSS)

The Clock security system can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE oscillator clock, this oscillator is automatically disabled and an interrupt is generated to inform the software about the failure (Clock Security System Interrupt, CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex™-M3 NMI (Non-Maskable Interrupt) exception vector.

*Note:* Once the CSS is enabled and if the HSE clock fails, the CSS interrupt occurs and an NMI is automatically generated. The NMI will be executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, in the NMI ISR must clear the CSS interrupt by setting the CSSC bit in the RCC\_CIR register.

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock, and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the MSI oscillator and the disabling of the external HSE oscillator. If the HSE oscillator clock is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

#### 4.2.10 RTC and LCD clock

The RTC and LCD have the same clock source which can be either the LSE, the LSI, or the HSE 1 MHz clock (HSE divided by a programmable prescaler). It is selected by programming the RTCSEL[1:0] bits in the RCC\_CSR register (see [Section 4.3.14](#)) and the RTCPRE[1:0] bits in the RCC\_CR register (see [Section 4.3.1](#)).

Once the RTC and LCD clock source have been selected, the only possible way of modifying the selection is to set the RTCRST bit in the RCC\_CSR register, or by a POR.

If the LSE or LSI is used as RTC clock source, the RTC continues to work in Stop and Standby low power modes, and can be used as wakeup source. However, when the HSE is the RTC clock source, the RTC cannot be used in the Stop and Standby low power modes. The LCD can however be used in the Stop low power mode if the LSE or LSI is used as the RTC clock source.

*Note:* To be able to read the RTC calendar register when the APB1 clock frequency is less than seven times the RTC clock frequency ( $7 \cdot RTCLK$ ), the software must read the calendar time and date registers twice.

*If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done.*

#### 4.2.11 Watchdog clock

If the Independent watchdog (IDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator temporization, the clock is provided to the IWDG.

#### 4.2.12 Clock-out capability

The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin (PA8) using a configurable prescaler (1, 2, 4, 8, or 16). The configuration registers of the corresponding GPIO port must be programmed in alternate function mode. One of 7 clock signals can be selected as the MCO clock:

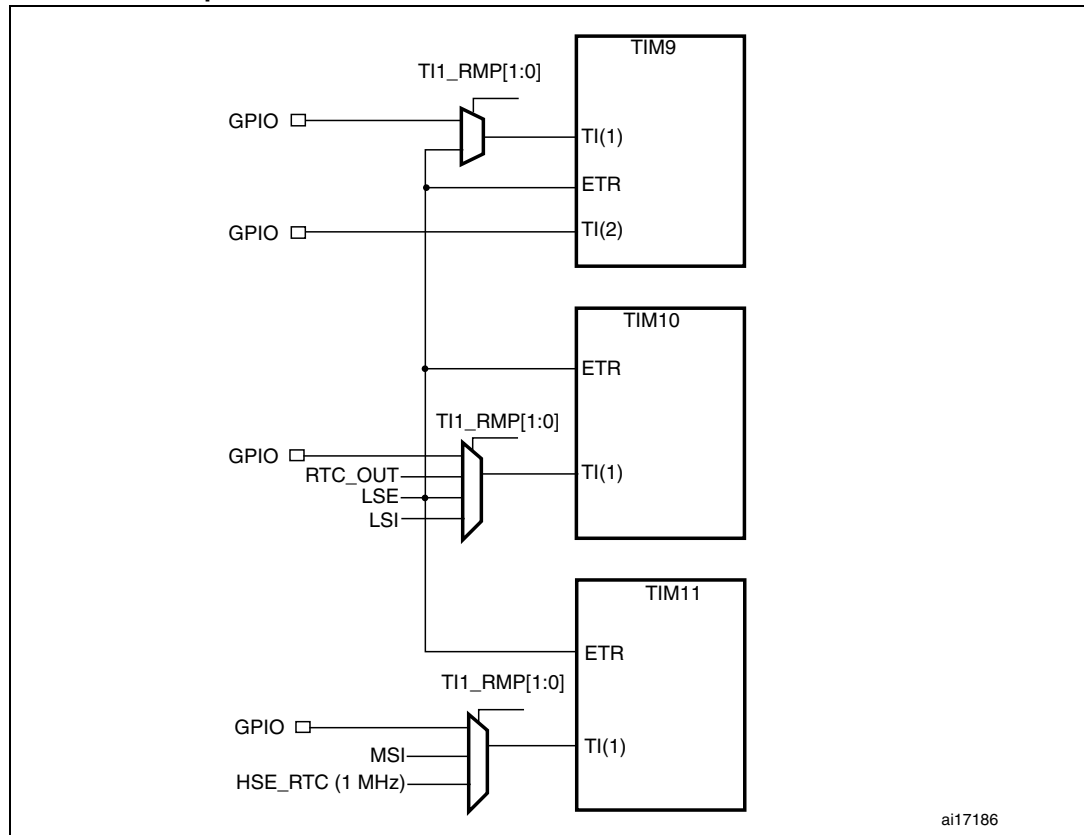

- SYSCLK
- HSI
- MSI
- HSE
- PLL
- LSI
- LSE

The selection is controlled by the MCOSEL[2:0] bits of the RCC\_CFGR register (see [Section 4.3.3](#)).

#### 4.2.13 Internal/external clock measurement with TIM9/TIM10/TIM11

It is possible to indirectly measure the frequency of all on-board clock source generators by means of the TIM9/TIM10/TIM11 channel 1 input capture, as represented on [Figure 12](#).

**Figure 12. Using the TIM9/TIM10/TIM11 channel 1 input capture to measure frequencies**

Each timer has an input multiplexer that selects which of the I/O or the internal clock is to trigger the input capture. This selection is performed through the TI1\_RMP [1:0] bits in the TIMx\_OR register.

For TIM9 and TIM10, the primary purpose of connecting the LSE to the channel 1 input capture is to be able to precisely measure the HSI and MSI system clocks (for this, either the HSI or MSI should be used as the system clock source). The number of HSI (MSI, respectively) clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm's), it is possible to determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process- and/or temperature- and voltage-related frequency deviations.

The MSI and HSI oscillators both have dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (e.g. the HSI/LSE ratio): the precision is therefore closely related to the ratio between the two clock sources. The higher the ratio, the better the measurement.

It is however not possible to have a good enough resolution when the MSI clock is low (typically below 1 MHz). In this case, it is advised to:

- accumulate the results of several captures in a row
- use the timer's input capture prescaler (up to 1 capture every 8 periods)
- use the RTC\_OUT signal at 512 Hz (when the RTC is clocked by the LSE) as the input for the channel1 input capture. This improves the measurement precision

TIM10 can also be used to measure the LSI: this is useful for applications with no crystal. The ultralow power LSI oscillator has a wide manufacturing process deviation: by measuring it as a function of the HSI clock source, it is possible to determine its frequency with the precision of the HSI.

Finally, TIM11 has two other sources. TIM11 can use the MSI just like TIM10 uses the LSI for crystal-less applications. The HSE\_RTC frequency (HSE divided by a programmable prescaler) being relatively high (1MHz), the relative frequency measurement is not very precise, so its main purpose is to have a rough indication of the external crystal frequency. This is useful for instance to meet the requirements of the IEC 60730/IEC 61335 standards, which requires to be able to determine harmonic or subharmonic frequencies ( $-50/+100\%$  deviations).

#### 4.2.14 Clock-independent system clock sources for TIM9/TIM10/TIM11

In a number of applications using the 32.768 kHz clock as a time base for the RTC, it is interesting to have time bases that work completely independently of the system clock. This allows the scheduling of tasks without having to take into account the processor state (the processor may be stopped or executing at low, medium or full speed).

For this purpose, the LSE clock is internally redirected to the 3 timers' ETR inputs, which are used as additional clock sources, as shown in [Figure 12 on page 80](#). This gives up to three independent time bases (using the auto-reload feature) with 1 or 2 compare additional channels for fractional events. For instance, the TIM9's auto-reload interrupt can be programmed for a 1 second tick interrupt with an additional interrupt occurring 250 ms after the main tick.

*Note:* In this configuration, make sure that you have at least a ratio of 2 between the external clock (LSE) and the APB clock. If the application uses an APB clock frequency lower than twice the LSE clock frequency (typically LSE = 32.768 kHz, so twice LSE = 65.536 kHz), it is mandatory to use the external trigger prescaler feature of the timer: it can divide the ETR clock by up to 8.

### 4.3 RCC registers

Refer to [Section 1.1](#) for a list of abbreviations used in register descriptions.

#### 4.3.1 Clock control register (RCC\_CR)

Address offset: 0x00

Reset value: 0x0000 0300

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	RTCPRE[1:0]		CSS ON	Reserved			PLL RDY	PLLON	Reserved				HSE BYP	HSE RDY	HSE ON
	rw	rw	rw				r	rw					rw	r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						MSI RDY	MSION	Reserved				HSI RDY	HSION		
						r	rw					r	rw		

Bit 31 Reserved, always read as 0

Bits 30:29 **RTCPRE[1:0]** RTC/LCD prescaler

These bits are set and reset by software to obtain a 1 MHz clock from HSE. This prescaler cannot be modified if HSE is enabled (HSEON = 1).

- 00: HSE is divided by 2 for RTC/LCD clock
- 01: HSE is divided by 4 for RTC/LCD clock
- 10: HSE is divided by 8 for RTC/LCD clock
- 11: HSE is divided by 16 for RTC/LCD clock

Bit 28 **CSSON**: Clock security system enable

This bit is set and cleared by software to enable the clock security system (CSS). When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if an oscillator failure is detected.

- 0: Clock security system OFF (clock detector OFF)
- 1: Clock security system ON (clock detector ON if HSE oscillator is stable, OFF otherwise)

Bit 27:26 Reserved, always read as 0

Bit 25 **PLL RDY**: PLL clock ready flag

This bit is set by hardware to indicate that the PLL is locked.

- 0: PLL unlocked
- 1: PLL locked

Bit 24 **PLLON**: PLL enable

This bit is set and cleared by software to enable PLL.

Cleared by hardware when entering Stop or Standby mode. This bit can not be reset if the PLL clock is used as system clock or is selected to become the system clock.

- 0: PLL OFF
- 1: PLL ON

Bits 23:19 Reserved, always read as 0

- Bit 18 **HSEBYP**: HSE clock bypass  
This bit is set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit, to be used by the device.  
The HSEBYP bit can be written only if the HSE oscillator is disabled.  
0: HSE oscillator not bypassed  
1: HSE oscillator bypassed with an external clock
- Bit 17 **HSERDY**: HSE clock ready flag  
This bit is set by hardware to indicate that the HSE oscillator is stable. After the HSION bit is cleared, HSERDY goes low after 6 HSE oscillator clock cycles.  
0: HSE oscillator not ready  
1: HSE oscillator ready
- Bit 16 **HSEON**: HSE clock enable  
This bit is set and cleared by software.  
Cleared by hardware to stop the HSE oscillator when entering Stop or Standby mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.  
0: HSE oscillator OFF  
1: HSE oscillator ON
- Bits 15:10 Reserved, always read as 0
- Bit 9 **MSIRDY**: MSI clock ready flag  
This bit is set by hardware to indicate that the MSI oscillator is stable.  
0: MSI oscillator not ready  
1: MSI oscillator ready  
*Note: Once the MSION bit is cleared, MSIRDY goes low after 6 MSI clock cycles.*
- Bit 8 **MSION**: MSI clock enable  
This bit is set and cleared by software.  
Set by hardware to force the MSI oscillator ON when exiting from Stop or Standby mode, or in case of a failure of the HSE oscillator used directly or indirectly as system clock. This bit cannot be cleared if the MSI is used as system clock.  
0: MSI oscillator OFF  
1: MSI oscillator ON
- Bits 7:2 Reserved, always read as 0
- Bit 1 **HSIRDY**: Internal high-speed clock ready flag  
This bit is set by hardware to indicate that the HSI oscillator is stable. After the HSION bit is cleared, HSIRDY goes low after 6 HSI clock cycles.  
0: HSI oscillator not ready  
1: HSI oscillator ready
- Bit 0 **HSION**: Internal high-speed clock enable  
This bit is set and cleared by software.  
This bit cannot be cleared if the HSI is used directly or indirectly as the system clock.  
0: HSI oscillator OFF  
1: HSI oscillator ON

### 4.3.2 Internal clock sources calibration register (RCC\_ICSCR)

Address offset: 0x04

Reset value: 0x00XX B0XX where X is undefined.

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSITRIM[7:0]								MSICAL[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSIRANGE[2:0]			HSITRIM[4:0]					HSICAL[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	r	r	r	r	r

Bits 31:24 **MSITRIM[7:0]**: MSI clock trimming

These bits are set by software to adjust MSI calibration.

These bits provide an additional user-programmable trimming value that is added to the MSICAL[7:0] bits. They can be programmed to compensate for the variations in voltage and temperature that influence the frequency of the internal MSI RC.

Bits 23:16 **MSICAL[7:0]**: MSI clock calibration

These bits are automatically initialized at startup.

Bits 15:13 **MSIRANGE[2:0]**: MSI clock ranges

These bits are set by software to choose the frequency range of MSI.7 frequency ranges are available:

- 000: range 0 around 65.536 kHz
- 001: range 1 around 131.072 kHz
- 010: range 2 around 262.144 kHz
- 011: range 3 around 524.288 kHz
- 100: range 4 around 1.048 MHz
- 101: range 5 around 2.097 MHz (reset value)
- 110: range 6 around 4.194 MHz
- 111: not allowed

Bits 12:8 **HSITRIM[4:0]**: High speed internal clock trimming

These bits provide an additional user-programmable trimming value that is added to the HSICAL[7:0] bits. They can be programmed to be compensated for the variations in voltage and temperature that influence the frequency of the internal HSI RC.

Bits 7:0 **HSICAL[7:0]** Internal high speed clock calibration

These bits are initialized automatically at startup.

### 4.3.3 Clock configuration register (RCC\_CFGR)

Address offset: 0x08

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2, word, half-word and byte access

1 or 2 wait states inserted only if the access occurs during clock source switch.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	MCOPRE[2:0]			Res.	MCOSEL[2:0]			PLLDIV[1:0]		PLLMUL[3:0]				Res.	PLL SRC
	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		PPRE2[2:0]			PPRE1[2:0]			HPRE[3:0]				SWS[1:0]		SW[1:0]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	rw	rw

Bits 31 Reserved, always read as 0.

Bits 30:28 **MCOPRE[2:0]**: Microcontroller clock output prescaler

These bits are set and cleared by software.

It is highly recommended to change this prescaler before MCO output is enabled.

000: MCO is divided by 1

001: MCO is divided by 2

010: MCO is divided by 4

011: MCO is divided by 8

100: MCO is divided by 16

Others: not allowed

Bits 27 Reserved, always read as 0.

Bits 26:24 **MCOSEL[2:0]**: Microcontroller clock output selection

These bits are set and cleared by software.

000: MCO output disabled, no clock on MCO

001: SYSCLK clock selected

010: HSI oscillator clock selected

011: MSI oscillator clock selected

100: HSE oscillator clock selected

101: PLL clock selected

110: LSI oscillator clock selected

111:LSE oscillator clock selected

*Note: This clock output may have some truncated cycles at startup or during MCO clock source switching.*

Bits 23:22 **PLLDIV[1:0]**: PLL output division

These bits are set and cleared by software to control PLL output clock division from PLL VCO clock. These bits can be written only when the PLL is disabled.

00: not allowed

01: PLL clock output = PLLVCO / 2

10: PLL clock output = PLLVCO / 3

11: PLL clock output = PLLVCO / 4

**Bits 21:18 PLLMUL[3:0]:** PLL multiplication factor

These bits are written by software to define the PLL multiplication factor to generate the PLL VCO clock. These bits can be written only when the PLL is disabled.

0000: PLLVCO = PLL clock entry x 3  
0001: PLLVCO = PLL clock entry x 4  
0010: PLLVCO = PLL clock entry x 6  
0011: PLLVCO = PLL clock entry x 8  
0100: PLLVCO = PLL clock entry x 12  
0101: PLLVCO = PLL clock entry x 16  
0110: PLLVCO = PLL clock entry x 24  
0111: PLLVCO = PLL clock entry x 32  
1000: PLLVCO = PLL clock entry x 48  
others: not allowed

**Caution:** The PLL VCO clock frequency must not exceed 96 MHz when the product is in Range 1, 48 MHz when the product is in Range 2 and 24 MHz when the product is in Range 3.

Bit 17 Reserved, always read as 0

**Bit 16 PLLSRC:** PLL entry clock source

This bit is set and cleared by software to select PLL clock source. This bit can be written only when PLL is disabled.

0: HSI oscillator clock selected as PLL input clock  
1: HSE oscillator clock selected as PLL input clock

*Note: The PLL minimum input clock frequency is 2 MHz.*

Bits 15:14 Reserved, always read as 0

**Bits 13:11 PPRE2[2:0]:** APB high-speed prescaler (APB2)

These bits are set and cleared by software to control the division factor of the APB high-speed clock (PCLK2).

0xx: HCLK not divided  
100: HCLK divided by 2  
101: HCLK divided by 4  
110: HCLK divided by 8  
111: HCLK divided by 16

**Bits 10:8 PPRE1[2:0]:** APB low-speed prescaler (APB1)

These bits are set and cleared by software to control the division factor of the APB low-speed clock (PCLK1).

0xx: HCLK not divided  
100: HCLK divided by 2  
101: HCLK divided by 4  
110: HCLK divided by 8  
111: HCLK divided by 16

Bits 7:4 **HPRE[3:0]**: AHB prescaler

These bits are set and cleared by software to control the division factor of the AHB clock.

**Caution:** Depending on the device voltage range, the software has to set correctly these bits to ensure that the system frequency does not exceed the maximum allowed frequency (for more details please refer to the Dynamic voltage scaling management section in the PWR chapter.) After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value has been taken into account.

- 0xxx: SYSCLK not divided
- 1000: SYSCLK divided by 2
- 1001: SYSCLK divided by 4
- 1010: SYSCLK divided by 8
- 1011: SYSCLK divided by 16
- 1100: SYSCLK divided by 64
- 1101: SYSCLK divided by 128
- 1110: SYSCLK divided by 256
- 1111: SYSCLK divided by 512

Bits 3:2 **SWS[1:0]**: System clock switch status

These bits are set and cleared by hardware to indicate which clock source is used as system clock.

- 00: MSI oscillator used as system clock
- 01: HSI oscillator used as system clock
- 10: HSE oscillator used as system clock
- 11: PLL used as system clock

Bits 1:0 **SW[1:0]**: System clock switch

These bits are set and cleared by software to select SYSCLK source.

Set by hardware to force MSI selection when leaving Stop and Standby mode or in case of failure of the HSE oscillator used directly or indirectly as system clock (if the Clock Security System is enabled).

- 00: MSI oscillator used as system clock
- 01: HSI oscillator used as system clock
- 10: HSE oscillator used as system clock
- 11: PLL used as system clock

### 4.3.4 Clock interrupt register (RCC\_CIR)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								CSSC	Res.	MSI RDYC	PLL RDYC	HSE RDYC	HSI RDYC	LSE RDYC	LSI RDYC
								w		w	w	w	w	w	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		MSI RDYIE	PLL RDYIE	HSE RDYIE	HSI RDYIE	LSE RDYIE	LSI RDYIE	CSSF	Res.	MSI RDYF	PLL RDYF	HSE RDYF	HSI RDYF	LSE RDYF	LSI RDYF
		rw	rw	rw	rw	rw	rw	r		r	r	r	r	r	r

- Bits 31:24 Reserved, always read as 0.
- Bit 23 **CSSC**: Clock security system interrupt clear  
This bit is set by software to clear the CSSF flag.  
0: No effect  
1: Clear CSSF flag
- Bit 22 Reserved, always read as 0.
- Bit 21 **MSIRDYC**: MSI ready interrupt clear  
This bit is set by software to clear the MSIRDYF flag.  
0: No effect  
1: MSIRDYF cleared
- Bit 20 **PLLRDYC**: PLL ready interrupt clear  
This bit is set by software to clear the PLLRDYF flag.  
0: No effect  
1: PLLRDYF cleared
- Bit 19 **HSERDYC**: HSE ready interrupt clear  
This bit is set by software to clear the HSERDYF flag.  
0: No effect  
1: HSERDYF cleared
- Bit 18 **HSIRDYC**: HSI ready interrupt clear  
This bit is set software to clear the HSIRDYF flag.  
0: No effect  
1: HSIRDYF cleared
- Bit 17 **LSERDYC**: LSE ready interrupt clear  
This bit is set by software to clear the LSERDYF flag.  
0: No effect  
1: LSERDYF cleared
- Bit 16 **LSIRDYC**: LSI ready interrupt clear  
This bit is set by software to clear the LSIRDYF flag.  
0: No effect  
1: LSIRDYF cleared
- Bits 15:14 Reserved, always read as 0.
- Bit 12 **MSIRDYIE**: MSI ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the MSI oscillator stabilization.  
0: MSI ready interrupt disabled  
1: MSI ready interrupt enabled
- Bit 12 **PLLRDYIE**: PLL ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by PLL lock.  
0: PLL lock interrupt disabled  
1: PLL lock interrupt enabled
- Bit 11 **HSERDYIE**: HSE ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.  
0: HSE ready interrupt disabled  
1: HSE ready interrupt enabled

- Bit 10 **HSIRDYIE**: HSI ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the HSI oscillator stabilization.  
0: HSI ready interrupt disabled  
1: HSI ready interrupt enabled
- Bit 9 **LSERDYIE**: LSE ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.  
0: LSE ready interrupt disabled  
1: LSE ready interrupt enabled
- Bit 8 **LSIRDYIE**: LSI ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by LSI oscillator stabilization.  
0: LSI ready interrupt disabled  
1: LSI ready interrupt enabled
- Bit 7 **CSSF**: Clock security system interrupt flag  
This bit is set by hardware when a failure is detected in the HSE oscillator.  
It is cleared by software by setting the CSSC bit.  
0: No clock security interrupt caused by HSE clock failure  
1: Clock security interrupt caused by HSE clock failure
- Bit 6 Reserved, always read as 0.
- Bit 5 **MSIRDYF**: MSI ready interrupt flag  
This bit is set by hardware when the MSI becomes stable and MSIRDYDIE is set.  
It is cleared by software setting the MSIRDYC bit.  
0: No clock ready interrupt caused by the MSI  
1: Clock ready interrupt caused by the MSI
- Bit 4 **PLLRDYF**: PLL ready interrupt flag  
This bit is set by hardware when the PLL locks and PLLRDYDIE is set.  
It is cleared by software setting the PLLRDYC bit.  
0: No clock ready interrupt caused by PLL lock  
1: Clock ready interrupt caused by PLL lock
- Bit 3 **HSERDYF**: HSE ready interrupt flag  
This bit is set by hardware when HSE becomes stable and HSERDYDIE is set.  
It is cleared by software setting the HSERDYC bit.  
0: No clock ready interrupt caused by the HSE  
1: Clock ready interrupt caused by the HSE
- Bit 2 **HSIRDYF**: HSI ready interrupt flag  
This bit is set by hardware when the HSI becomes stable and HSIRDYDIE is set.  
It is cleared by software setting the HSIRDYC bit.  
0: No clock ready interrupt caused by the HSI  
1: Clock ready interrupt caused by the HSI
- Bit 1 **LSERDYF**: LSE ready interrupt flag  
This bit is set by hardware when the LSE becomes stable and LSERDYDIE is set.  
It is cleared by software setting the LSERDYC bit.  
0: No clock ready interrupt caused by the LSE  
1: Clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag  
 This bit is set by hardware when the LSI becomes stable and LSIRDYDIE is set.  
 It is cleared by software setting the LSIRDYC bit.  
 0: No clock ready interrupt caused by the LSI  
 1: Clock ready interrupt caused by the LSI

### 4.3.5 AHB peripheral reset register (RCC\_AHBRSTR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							DMA1RST	Reserved							
							rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLITFRST	Reserved		CRCRST	Reserved						GPIOH RST	GPIOE RST	GPIOD RST	GPIOC RST	GPIOB RST	GPIOA RST
rw			rw							rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, always read as 0.

Bit 24 **DMA1RST**: DMA1 reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset DMA1

Bits 23:16 Reserved, always read as 0.

Bit 15 **FLITFRST**: FLITF reset  
 This bit is set and cleared by software. The FLITF reset can be enabled only when the Flash memory is in power down mode.  
 0: No effect  
 1: Reset FLITF

Bits 14:13 Reserved, always read as 0.

Bit 12 **CRCRST**: CRC reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset CRC

Bits 11:6 Reserved, always read as 0.

Bit 5 **GPIOHRST**: IO port H reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset

Bit 4 **GPIOERST**: IO port E reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset IO port E

- Bit 3 **GPIODRST**: IO port D reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset IO port D
- Bit 2 **GPIOCRST**: IO port C reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset IO port C
- Bit 1 **GPIOBRST**: IO port B reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset IO port B
- Bit 0 **GPIOARST**: IO port A reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset IO port A

### 4.3.6 APB2 peripheral reset register (RCC\_APB2RSTR)

Address offset: 0x14

Reset value: 0x00000 0000

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Reserved																
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	rw		rw				rw					rw	rw	rw		rw

- Bits 31:15 Reserved, always read as 0.
- Bit 14 **USART1RST**: USART1 reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset USART1
- Bit 13 Reserved, always read as 0.
- Bit 12 **SPI1RST**: SPI 1 reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset SPI 1
- Bits 11:10 Reserved, always read as 0.
- Bit 9 **ADC1RST**: ADC1 interface reset  
 This bit is set and cleared by software.  
 0: No effect  
 1: Reset ADC1 interface
- Bits 8:5 Reserved, always read as 0.

- Bit 4 **TIM11RST**: TIM11 timer reset  
Set and cleared by software.  
0: No effect  
1: Reset TIM11 timer
- Bit 3 **TIM10RST**: TIM10 timer reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset TIM10 timer
- Bit 2 **TIM9RST**: TIM9 timer reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset TIM9 timer
- Bit 1 Reserved, always read as 0.
- Bit 0 **SYSCFGRST**: System configuration controller reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset System configuration controller

### 4.3.7 APB1 peripheral reset register (RCC\_APB1RSTR)

Address offset: 0x18

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

- Bit 31 **COMPRST**: COMP interface reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset COMP interface
- Bits 30 Reserved, always read as 0.
- Bit 29 **DACRST**: DAC interface reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset DAC interface
- Bit 28 **PWRRST**: Power interface reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset power interface
- Bits 27:24 Reserved, always read as 0.

- Bit 23 **USBRST**: USB reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset USB
- Bit 22 **I2C2RST**: I<sup>2</sup>C 2 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset I<sup>2</sup>C 2
- Bit 21 **I2C1RST**: I<sup>2</sup>C 1 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset I<sup>2</sup>C 1
- Bits 20:19 Reserved, always read as 0.
- Bit 18 **USART3RST**: USART 3 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset USART 3
- Bit 17 **USART2RST**: USART 2 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset USART 2
- Bits 16:15 Reserved, always read as 0.
- Bit 14 **SPI2RST**: SPI 2 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset SPI 2
- Bits 13:12 Reserved, always read as 0.
- Bit 11 **WWDGRST**: Window watchdog reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset window watchdog
- Bits 10 Reserved, always read as 0.
- Bit 9 **LCDRST**: LCD reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset LCD
- Bits 8:6 Reserved, always read as 0.
- Bit 5 **TIM7RST**: Timer 7 reset  
This bit is set and cleared by software.  
0: No effect  
1: Reset timer 7
- Bit 4 **TIM6RST**: Timer 6 reset  
Set and cleared by software.  
0: No effect  
1: Reset timer 6

- Bit 3 Reserved, always read as 0.
- Bit 2 **TIM4RST**: Timer 4 reset  
Set and cleared by software.  
0: No effect  
1: Reset timer 4
- Bit 1 **TIM3RST**: Timer 3 reset  
Set and cleared by software.  
0: No effect  
1: Reset timer 3
- Bit 0 **TIM2RST**: Timer 2 reset  
Set and cleared by software.  
0: No effect  
1: Reset timer 2

### 4.3.8 AHB peripheral clock enable register (RCC\_AHBENR)

Address offset: 0x1C

Reset value: 0x0000 8000

Access: no wait state, word, half-word and byte access

*Note: When the peripheral clock is not active, the peripheral register values may not be readable by software and the returned value is always 0x0.*

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Reserved							DMA1EN	Reserved

rw			rw							rw	rw	rw	rw	rw	rw	

- Bits 31:25 Reserved, always read as 0.
- Bit 24 **DMA1EN**: DMA1 clock enable  
This bit is set and cleared by software.  
0: DMA1 clock disabled  
1: DMA1 clock enabled
- Bits 23:16 Reserved, always read as 0.
- Bit 15 **FLITFEN**: FLITF clock enable  
This bit can be written only when the Flash memory is in power down mode.  
0: FLITF clock disabled  
1: FLITF clock enabled
- Bits 14:13 Reserved, always read as 0.
- Bit 12 **CRCEN**: CRC clock enable  
This bit is set and cleared by software.  
0: CRC clock disabled  
1: CRC clock enabled
- Bits 11:8 Reserved, always read as 0.

- Bit 5 **GPIOHEN**: IO port H clock enable  
 This bit is set and cleared by software.  
 0: IO port H clock disabled  
 1: IO port H clock enabled
- Bit 4 **GPIOEEN**: IO port E clock enable  
 This bit is set and cleared by software.  
 0: IO port E clock disabled  
 1: IO port E clock enabled
- Bit 3 **GPIODEN**: IO port D clock enable  
 Set and cleared by software.  
 0: IO port D clock disabled  
 1: IO port D clock enabled
- Bit 2 **GPIOCEN**: IO port C clock enable  
 This bit is set and cleared by software.  
 0: IO port C clock disabled  
 1: IO port C clock enabled
- Bit 1 **GPIOBEN**: IO port B clock enable  
 This bit is set and cleared by software.  
 0: IO port B clock disabled  
 1: IO port B clock enabled
- Bit 0 **GPIOAEN**: IO port A clock enable  
 This bit is set and cleared by software.  
 0: IO port A clock disabled  
 1: IO port A clock enabled

### 4.3.9 APB2 peripheral clock enable register (RCC\_APB2ENR)

Address: 0x20

Reset value: 0x0000 0000

Access: word, half-word and byte access

No wait states, except if the access occurs while an access to a peripheral in the APB2 domain is on going. In this case, wait states are inserted until the access to APB2 peripheral is finished.

*Note:* When the peripheral clock is not active, the peripheral register values may not be readable by software and the returned value is always 0x0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Reserved																
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	rw		rw									rw	rw	rw		rw

Bits 31:15 Reserved, always read as 0.

- Bit 14 **USART1EN**: USART1 clock enable  
This bit is set and cleared by software.  
0: USART1 clock disabled  
1: USART1 clock enabled
- Bit 13 Reserved, always read as 0.
- Bit 12 **SPI1EN**: SPI 1 clock enable  
This bit is set and cleared by software.  
0: SPI 1 clock disabled  
1: SPI 1 clock enabled
- Bits 11:10 Reserved, always read as 0.
- Bit 9 **ADC1EN**: ADC1 interface clock enable  
This bit is set and cleared by software.  
0: ADC1 interface disabled  
1: ADC1 interface clock enabled
- Bits 8:5 Reserved, always read as 0.
- Bit 4 **TIM11EN**: TIM11 timer clock enable  
This bit is set and cleared by software.  
0: TIM11 timer clock disabled  
1: TIM11 timer clock enabled
- Bit 3 **TIM10EN**: TIM10 timer clock enable  
This bit is set and cleared by software.  
0: TIM10 timer clock disabled  
1: TIM10 timer clock enabled
- Bit 2 **TIM9EN**: TIM9 timer clock enable  
This bit is set and cleared by software.  
0: TIM9 timer clock disabled  
1: TIM9 timer clock enabled
- Bit 1 Reserved, always read as 0.
- Bit 0 **SYSCFGEN**: System configuration controller clock enable  
This bit is set and cleared by software.  
0: System configuration controller clock disabled  
1: System configuration controller clock enabled

### 4.3.10 APB1 peripheral clock enable register (RCC\_APB1ENR)

Address: 0x24

Reset value: 0x0000 0000

Access: word, half-word and byte access

No wait state, except if the access occurs while an access to a peripheral on APB1 domain is on going. In this case, wait states are inserted until this access to APB1 peripheral is finished.

*Note: When the peripheral clock is not active, the peripheral register values may not be readable by software and the returned value is always 0x0.*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
COMP EN	Res.	DAC EN	PWR EN	Reserved				USB EN	I2C2 EN	I2C1 EN	Reserved			USART3 EN	USART2 EN	Res.

Bit 31 **COMPEN**: COMP interface clock enable  
 This bit is set and cleared by software.  
 0: COMP interface clock disabled  
 1: COMP interface clock enable

Bits 30 Reserved, always read as 0.

Bit 29 **DACEN**: DAC interface clock enable  
 This bit is set and cleared by software.  
 0: DAC interface clock disabled  
 1: DAC interface clock enable

Bit 28 **PWREN**: Power interface clock enable  
 This bit is set and cleared by software.  
 0: Power interface clock disabled  
 1: Power interface clock enable

Bits 27:24 Reserved, always read as 0.

Bit 23 **USBEN**: USB clock enable  
 This bit is set and cleared by software.  
 0: USB clock disabled  
 1: USB clock enabled

Bit 22 **I2C2EN**: I<sup>2</sup>C 2 clock enable  
 This bit is set and cleared by software.  
 0: I<sup>2</sup>C 2 clock disabled  
 1: I<sup>2</sup>C 2 clock enabled

Bit 21 **I2C1EN**: I2C 1 clock enable  
 This bit is set and cleared by software.  
 0: I<sup>2</sup>C 1 clock disabled  
 1: I<sup>2</sup>C 1 clock enabled

Bits 20:19 Reserved, always read as 0.

- Bit 18 **USART3EN**: USART 3 clock enable  
This bit is set and cleared by software.  
0: USART 3 clock disabled  
1: USART 3 clock enabled
- Bit 17 **USART2EN**: USART 2 clock enable  
This bit is set and cleared by software.  
0: USART 2 clock disabled  
1: USART 2 clock enabled
- Bits 16:15 Reserved, always read as 0.
- Bit 14 **SPI2EN**: SPI 2 clock enable  
This bit is set and cleared by software.  
0: SPI 2 clock disabled  
1: SPI 2 clock enabled
- Bits 13:12 Reserved, always read as 0.
- Bit 11 **WWDGEN**: Window watchdog clock enable  
This bit is set and cleared by software.  
0: Window watchdog clock disabled  
1: Window watchdog clock enabled
- Bit 10 Reserved, always read as 0.
- Bit 9 **LCDEN**: LCD clock enable  
This bit is set and cleared by software.  
0: LCD clock disabled  
1: LCD clock enabled
- Bits 8:6 Reserved, always read as 0.
- Bit 5 **TIM7EN**: Timer 7 clock enable  
This bit is set and cleared by software.  
0: Timer 7 clock disabled  
1: Timer 7 clock enabled
- Bit 4 **TIM6EN**: Timer 6 clock enable  
This bit is set and cleared by software.  
0: Timer 6 clock disabled  
1: Timer 6 clock enabled
- Bit 3 Reserved, always read as 0.
- Bit 2 **TIM4EN**: Timer 4 clock enable  
This bit is set and cleared by software.  
0: Timer 4 clock disabled  
1: Timer 4 clock enabled
- Bit 1 **TIM3EN**: Timer 3 clock enable  
This bit is set and cleared by software.  
0: Timer 3 clock disabled  
1: Timer 3 clock enabled
- Bit 0 **TIM2EN**: Timer 2 clock enable  
This bit is set and cleared by software.  
0: Timer 2 clock disabled  
1: Timer 2 clock enabled

### 4.3.11 AHB peripheral clock enable in low power mode register (RCC\_AHBLPENR)

Address offset: 0x28

Reset value: 0x0101 903F

Access: no wait state, word, half-word and byte access

*Note: The peripheral clock is enabled in sleep mode only if it previously has been enabled in AHBENR register.*

31		30		29		28		27		26		25		24		23		22		21		20		19		18		17		16

Bit 24 **DMA1LPEN**: DMA1 clock enable during Sleep mode

This bit is set and cleared by software.

0: DMA1 clock disabled during Sleep mode

1: DMA1 clock enabled during Sleep mode

Bits 23:17 Reserved, always read as 0.

Bit 16 **SRAML PEN**: SRAM clock enable during Sleep mode

This bit is set and cleared by software.

0: SRAM clock disabled during Sleep mode

1: SRAM clock enabled during Sleep mode

Bit 15 **FLITFLPEN**: FLITF clock enable during Sleep mode

This bit can be written only when the Flash memory is in power down mode.

0: FLITF clock disabled during Sleep mode

1: FLITF clock enabled during Sleep mode

Bits 14:13 Reserved, always read as 0.

Bit 12 **CRCLPEN**: CRC clock enable during Sleep mode

This bit is set and cleared by software.

0: CRC clock disabled during Sleep mode

1: CRC clock enabled during Sleep mode

Bits 11:6 Reserved, always read as 0.

Bit 5 **GPIOHLPEN**: IO port H clock enable during Sleep mode

This bit is set and cleared by software.

0: IO port H clock disabled during Sleep mode

1: IO port H clock enabled during Sleep mode

Bit 4 **GPIOELPEN**: IO port E clock enable during Sleep mode

This bit is set and cleared by software.

0: IO port E clock disabled during Sleep mode

1: IO port E clock enabled during Sleep mode

- Bit 3 **GPIODLPEN**: IO port D clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port D clock disabled during Sleep mode  
 1: IO port D clock enabled during Sleep mode
- Bit 2 **GPIOCLPEN**: IO port C clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port C clock disabled during Sleep mode  
 1: IO port C clock enabled during Sleep mode
- Bit 1 **GPIOBLPEN**: IO port B clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port B clock disabled during Sleep mode  
 1: IO port B clock enabled during Sleep mode
- Bit 0 **GPIOALPEN**: IO port A clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: IO port A clock disabled during Sleep mode  
 1: IO port A clock enabled during Sleep mode

### 4.3.12 APB2 peripheral clock enable in low power mode register (RCC\_APB2LPENR)

Address: 0x2C

Reset value: 0x0000 521D

Access: no wait states, word, half-word and byte access

*Note: The peripheral clock is enabled in sleep mode only if it's previously has been enabled in APB2ENR register.*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

- Bit 14 **USART1LPEN**: USART1 clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: USART1 clock disabled during Sleep mode  
 1: USART1 clock enabled during Sleep mode

Bit 13 Reserved, always read as 0.

- Bit 12 **SPI1LPEN**: SPI 1 clock enable during Sleep mode  
 This bit is set and cleared by software.  
 0: SPI 1 clock disabled during Sleep mode  
 1: SPI 1 clock enabled during Sleep mode

Bits 11:10 Reserved, always read as 0.

Bit 9 **ADC1LPEN**: ADC1 interface clock enable during Sleep mode

- This bit is set and cleared by software.
- 0: ADC1 interface disabled during Sleep mode
- 1: ADC1 interface clock enabled during Sleep mode

Bits 8:5 Reserved, always read as 0.

Bit 4 **TIM11LPEN**: TIM11 timer clock enable during Sleep mode

- This bit is set and cleared by software.
- 0: TIM11 timer clock disabled during Sleep mode
- 1: TIM11 timer clock enabled during Sleep mode

Bit 3 **TIM10LPEN**: TIM10 timer clock enable during Sleep mode

- This bit is set and cleared by software.
- 0: TIM10 timer clock disabled during Sleep mode
- 1: TIM10 timer clock enabled during Sleep mode

Bit 2 **TIM9LPEN**: TIM9 timer clock enable during Sleep mode

- This bit is set and cleared by software.
- 0: TIM9 timer clock disabled during Sleep mode
- 1: TIM9 timer clock enabled during Sleep mode

Bit 1 Reserved, always read as 0.

Bit 0 **SYSCFGLPEN**: System configuration controller clock enable during Sleep mode

- This bit is set and cleared by software.
- 0: System configuration controller clock disabled during Sleep mode
- 1: System configuration controller clock enabled during Sleep mode

### 4.3.13 APB1 peripheral clock enable in low power mode register (RCC\_APB1LPENR)

Address: 0x30

Reset value: 0xB0E6 4A37

Access: no wait state, word, half-word and byte access

*Note: The peripheral clock is enabled in sleep mode only if it's previously has been enabled in APB1ENR register.*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **COMPLPEN**: COMP interface clock enable during Sleep mode

- This bit is set and cleared by software.
- 0: COMP interface clock disabled during Sleep mode
- 1: COMP interface clock enable during Sleep mode

Bits 30 Reserved, always read as 0.

- Bit 29 **DACL PEN**: DAC interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DAC interface clock disabled during Sleep mode  
1: DAC interface clock enable during Sleep mode
- Bit 28 **PWR LPEN**: Power interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Power interface clock disabled during Sleep mode  
1: Power interface clock enable during Sleep mode
- Bits 27:24 Reserved, always read as 0.
- Bit 23 **USBL PEN**: USB clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USB clock disabled during Sleep mode  
1: USB clock enabled during Sleep mode
- Bit 22 **I2C2 LPEN**: I<sup>2</sup>C 2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I<sup>2</sup>C 2 clock disabled during Sleep mode  
1: I<sup>2</sup>C 2 clock enabled during Sleep mode
- Bit 21 **I2C1 LPEN**: I<sup>2</sup>C 1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I<sup>2</sup>C 1 clock disabled during Sleep mode  
1: I<sup>2</sup>C 1 clock enabled during Sleep mode
- Bits 20:19 Reserved, always read as 0.
- Bit 18 **USART3 LPEN**: USART 3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART 3 clock disabled during Sleep mode  
1: USART 3 clock enabled during Sleep mode
- Bit 17 **USART2 LPEN**: USART 2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART 2 clock disabled during Sleep mode  
1: USART 2 clock enabled during Sleep mode
- Bits 16:15 Reserved, always read as 0.
- Bit 14 **SPI2 LPEN**: SPI 2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPI 2 clock disabled during Sleep mode  
1: SPI 2 clock enabled during Sleep mode
- Bits 13:12 Reserved, always read as 0.
- Bit 11 **WWDG LPEN**: Window watchdog clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Window watchdog clock disabled during Sleep mode  
1: Window watchdog clock enabled during Sleep mode
- Bit 10 Reserved, always read as 0.
- Bit 9 **LCD LPEN**: LCD clock enable during Sleep mode  
This bit is set and cleared by software.  
0: LCD clock disabled during Sleep mode  
1: LCD clock enabled during Sleep mode

Bits 8:6 Reserved, always read as 0.

Bit 5 **TIM7LPEN**: Timer 7 clock enable during Sleep mode

This bit is set and cleared by software.  
 0: Timer 7 clock disabled during Sleep mode  
 1: Timer 7 clock enabled during Sleep mode

Bit 4 **TIM6LPEN**: Timer 6 clock enable during Sleep mode

This bit is set and cleared by software.  
 0: Timer 6 clock disabled during Sleep mode  
 1: Timer 6 clock enabled during Sleep mode

Bit 3 Reserved, always read as 0.

Bit 2 **TIM4LPEN**: Timer 4 clock enable during Sleep mode

This bit is set and cleared by software.  
 0: Timer 4 clock disabled during Sleep mode  
 1: Timer 4 clock enabled during Sleep mode

Bit 1 **TIM3LPEN**: Timer 3 clock enable during Sleep mode

This bit is set and cleared by software.  
 0: Timer 3 clock disabled during Sleep mode  
 1: Timer 3 clock enabled during Sleep mode

Bit 0 **TIM2LPEN**: Timer 2 clock enable during Sleep mode

This bit is set and cleared by software.  
 0: Timer 2 clock disabled during Sleep mode  
 1: Timer 2 clock enabled during Sleep mode

### 4.3.14 Control/status register (RCC\_CSR)

Address: 0x34

Reset value: 0x0C00 0000,

Access: 0 ≤ wait state ≤ 3, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

*Note: 1 The LSEON, LSEBYP, RTCSEL and RTCEN bits in the RCC control and status register (RCC\_CSR) are in the RTC domain. As these bits are write protected after reset, the DBP bit in the Power control register (PWR\_CR) has to be set to be able to modify them. Refer to Section [RTC and RTC backup registers](#) for further information. These bits are only reset after a RTC domain reset (see [RTC and backup registers reset](#)). Any internal or external reset does not have any effect on them.*

Reserved					LSE BYP	LSE RDY	LSE ON	Reserved						LSI RDY	LSION
					rw	r	rw							r	rw

- Bit 31 **LPWRRSTF**: Low-power reset flag  
This bit is set by hardware when a Low-power management reset occurs.  
It is cleared by writing to the RMVF bit, or by a POR.  
0: No Low-power management reset occurred  
1: Low-power management reset occurred  
For further information on Low-power management reset, refer to [Low-power management reset](#).
- Bit 30 **WWDGRSTF**: Window watchdog reset flag  
This bit is set by hardware when a window watchdog reset occurs.  
It is cleared by writing to the RMVF bit, or by a POR.  
0: No window watchdog reset occurred  
1: Window watchdog reset occurred
- Bit 29 **IWDGRSTF**: Independent watchdog reset flag  
This bit is set by hardware when an independent watchdog reset from V<sub>DD</sub> domain occurs.  
It is cleared by writing to the RMVF bit, or by a POR.  
0: No watchdog reset occurred  
1: Watchdog reset occurred
- Bit 28 **SFTRSTF**: Software reset flag  
This bit is set by hardware when a software reset occurs.  
It is cleared by writing to the RMVF bit, or by a POR.  
0: No software reset occurred  
1: Software reset occurred
- Bit 27 **PORRSTF**: POR/PDR reset flag  
This bit is set by hardware when a POR/PDR reset occurs.  
It is cleared by writing to the RMVF bit.  
0: No POR/PDR reset occurred  
1: POR/PDR reset occurred
- Bit 26 **PINRSTF**: PIN reset flag  
This bit is set by hardware when a reset from the NRST pin occurs.  
It is cleared by writing to the RMVF bit, or by a POR.  
0: No reset from NRST pin occurred  
1: Reset from NRST pin occurred
- Bit 25 **OBLRSTF**: Options bytes loading reset flag  
This bit is set by hardware when an OBL reset occurs.  
It is cleared by writing to the RMVF bit, or by a POR.  
0: No OBL reset occurred  
1: OBL reset occurred
- Bit 24 **RMVF**: Remove reset flag  
This bit is set by software to clear the reset flags.  
0: No effect  
1: Clear the reset flags
- Bit 23 **RTCST**: RTC software reset  
This bit is set and cleared by software.  
0: Reset not activated  
1: Resets the RTC peripheral, its clock source selection and the backup registers.

**Bit 22 RTCEN:** RTC clock enable

This bit is set and cleared by software.

It is reset by setting the RTCRST bit or by a POR.

0: RTC clock disabled

1: RTC clock enabled

Bits 21:18 Reserved, always read as 0.

**Bits 17:16 RTCSEL[1:0]:** RTC and LCD clock source selection

These bits are set by software to select the clock source for the RTC.

Once the RTC and LCD clock source has been selected, the only possible way of modifying the selection is to set the RTCRST bit, or issuing a POR.

00: No clock

01: LSE oscillator clock used as RTC clock

10: LSI oscillator clock used as RTC clock

11: HSE oscillator clock divided by a programmable prescaler (selection through the RTCPRE[1:0] bits in the RCC clock control register (RCC\_CR)) used as the RTC clock

If the LSE or LSI is used as RTC clock source, the RTC continues to work in Stop and Standby low power modes, and can be used as wake-up source. However, when the HSE clock is used as RTC clock source, the RTC cannot be used in Stop and Standby low power modes.

Bits 15:11 Reserved, always read as 0.

**Bit 10 LSEBYP:** External low-speed oscillator bypass

This bit is set and cleared by software to bypass oscillator in debug mode. This bit can be written only when the LSE oscillator is disabled.

It is reset by setting the RTCRST bit or by a POR.

0: LSE oscillator not bypassed

1: LSE oscillator bypassed

**Bit 9 LSERDY:** External low-speed oscillator ready

This bit is set and cleared by hardware to indicate when the LSE oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after 6 LSE oscillator clock cycles.

It is reset by setting the RTCRST bit or by a POR.

0: External 32 kHz oscillator not ready

1: External 32 kHz oscillator ready

**Bit 8 LSEON:** External low-speed oscillator enable

This bit is set and cleared by software.

It is reset by setting the RTCRST bit or by a POR.

0: LSE oscillator OFF

1: LSE oscillator ON

Bits 7:2 Reserved, always read as 0.

**Bit 1 LSIRDY:** Internal low-speed oscillator ready

This bit is set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after 3 LSI oscillator clock cycles.

This bit is reset by system reset.

0: LSI oscillator not ready

1: LSI oscillator ready

Bit 0 **LSION**: Internal low-speed oscillator enable  
 This bit is set and cleared by software.  
 It is reset by system reset.  
 0: LSI oscillator OFF  
 1: LSI oscillator ON

### 4.3.15 RCC register map

The following table gives the RCC register map and the reset values.

**Table 17. RCC register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 5 General-purpose I/Os (GPIO)

### 5.1 GPIO introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR and GPIOx\_PUPDR), two 32-bit data registers (GPIOx\_IDR and GPIOx\_ODR), a 32-bit set/reset register (GPIOx\_BSRR), a 32-bit locking register (GPIOx\_LCKR) and two 32-bit alternate function selection register (GPIOx\_AFRH and GPIOx\_AFRL).

### 5.2 GPIO main features

- Up to 16 I/Os under control
- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx\_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx\_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx\_BSRR) for bitwise write access to GPIOx\_ODR
- Locking mechanism (GPIOx\_LCKR) provided to freeze the I/O configuration
- Analog function
- Alternate function input/output selection registers (at most 16 AFs per I/O)
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

### 5.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx\_BSRR register is to allow atomic read/modify accesses to any of the GPIO registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Figure 13 and Figure 14 show the basic structures of a standard and a 5 V tolerant I/O port bit, respectively. Table 21 gives the possible port bit configurations.

Figure 13. Basic structure of a standard I/O port bit

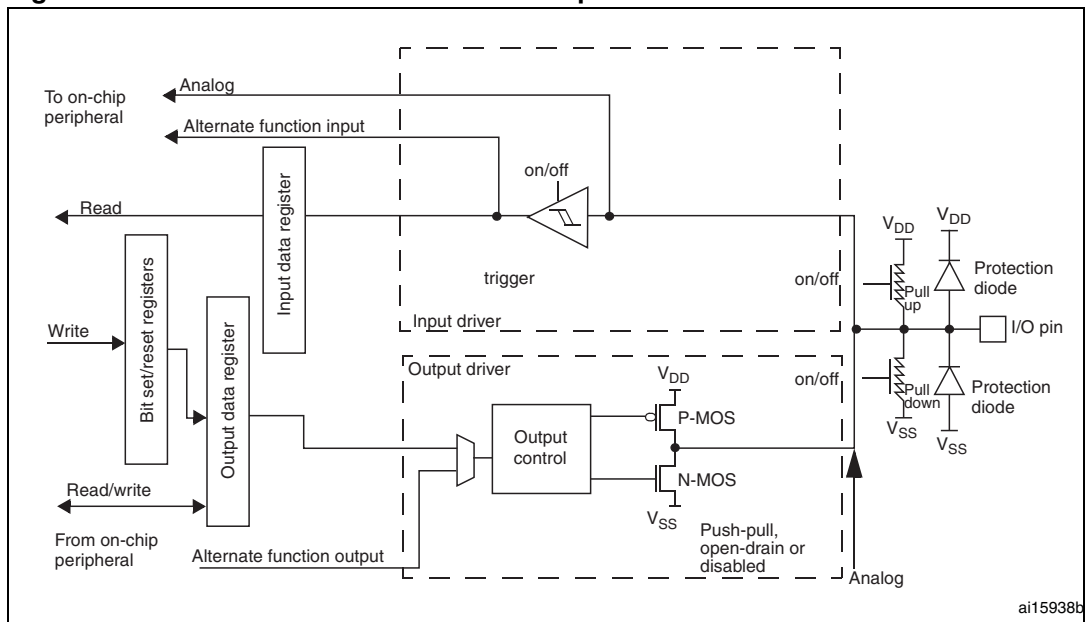

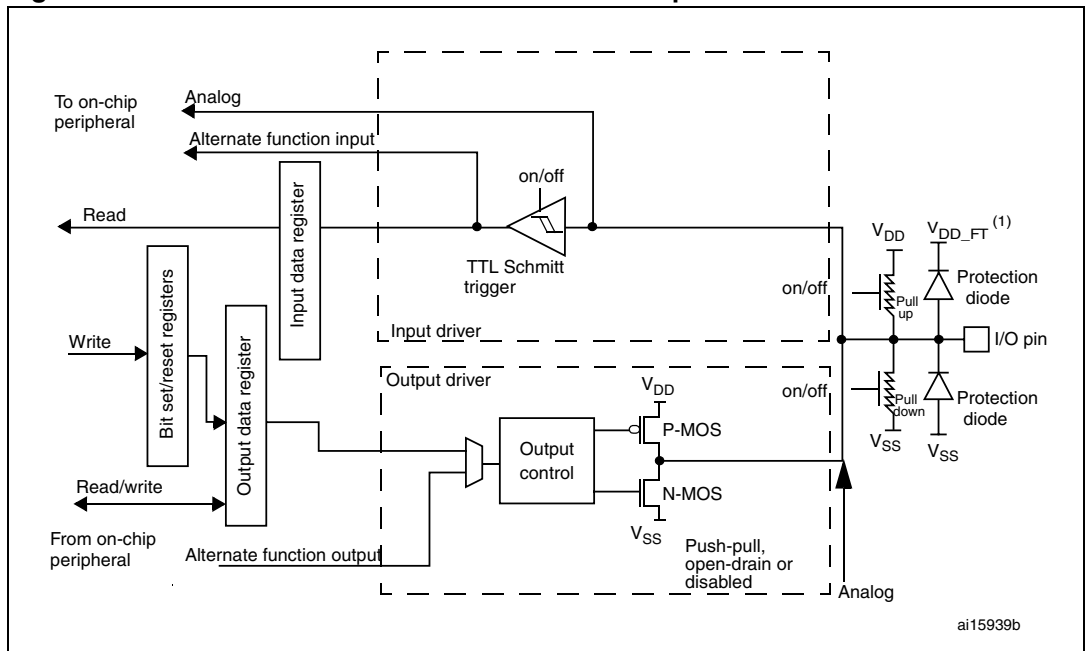

Figure 14. Basic structure of a five-volt tolerant I/O port bit

1.  $V_{DD\_FT}$  is a potential specific to five-volt tolerant I/Os and different from  $V_{DD}$ .

**Table 18. Port bit configuration table<sup>(1)</sup>**

MODER(i) [1:0]	OTYPER(i)	OSPEEDR(i) [B:A]		PUPDR(i) [1:0]		I/O configuration	
01	0	SPEED [B:A]		0	0	GP output	PP
	0			0	1	GP output	PP + PU
	0			1	0	GP output	PP + PD
	0			1	1	Reserved	
	1			0	0	GP output	OD
	1			0	1	GP output	OD + PU
	1			1	0	GP output	OD + PD
	1			1	Reserved (GP output OD)		
10	0	SPEED [B:A]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	Reserved		
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0		
	x	x	x	1	1		

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

### 5.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and the I/O ports are configured in input floating mode.

The JTAG pins are in input pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK in pull-down
- PA13: JTMS in pull-up
- PB4: NJTRST in pull-up

When the pin is configured as output, the value written to the output data register (GPIOx\_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the N-MOS is activated when 0 is output).

The input data register (GPIOx\_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx\_PUPDR register.

### 5.3.2 I/O pin multiplexer and mapping

The STM32L15xxx I/O pins are connected to onboard peripherals/modules through a multiplexer that allows only one peripheral's alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals sharing the same I/O pin.

Each I/O pin has a multiplexer with sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx\_AFRL (for pin 0 to 7) and GPIOx\_AFRH (for pin 8 to 15) registers:

- After reset all I/Os are connected to the system's alternate function 0 (AF0)
- The peripherals' alternate functions are mapped from AF1 to AF14
- Cortex-M3 EVENTOUT is mapped on AF15

This structure is shown in [Figure 15](#) below.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, you have to proceed as follows:

- **System function:** you have to connect the I/O to AF0 and configure it depending on the function used:
  - JTAG/SWD, after each device reset these pins are assigned as dedicated pins immediately usable by the debugger host (not controlled by the GPIO controller)
  - RTC\_AF1: refer to [Table 20: RTC\\_AF1 pin](#) for more details about this pin configuration
  - RTC\_50Hz: this pin should be configured in Input floating mode
  - MCO: this pin has to be configured in alternate function mode.

*Note:* You can disable some or all of the JTAG/SWD pins and so release the associated pins for GPIO usage.

For more details please refer to [Section 4.2.12: Clock-out capability](#).

**Table 19. Flexible SWJ-DP pin assignment**

Available debug ports	SWJ I/O pin assigned				
	PA13 / JTMS / SWDIO	PA14 / JTCK / SWCLK	PA15 / JTDI	PB3 / JTDO	PB4 / NJTRST
Full SWJ (JTAG-DP + SW-DP) - Reset state	X	X	X	X	X

**Table 19. Flexible SWJ-DP pin assignment (continued)**

Available debug ports	SWJ I/O pin assigned				
	PA13 / JTMS / SWDIO	PA14 / JTCK / SWCLK	PA15 / JTDI	PB3 / JTDO	PB4 / NJTRST
Full SWJ (JTAG-DP + SW-DP) but without NJTRST	X	X	X	X	
JTAG-DP Disabled and SW-DP Enabled	X	X			
JTAG-DP Disabled and SW-DP Disabled	Released				

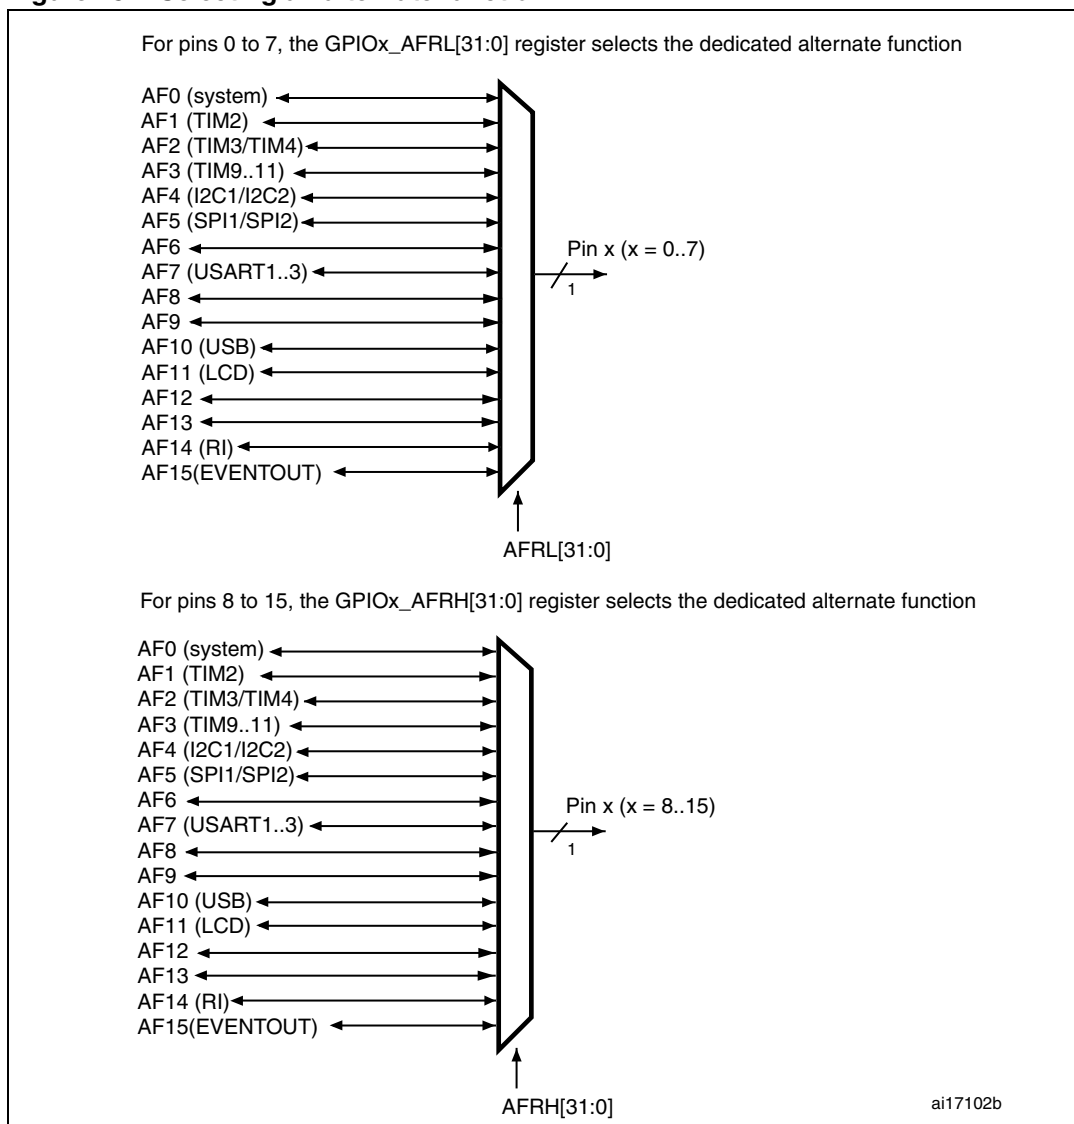

- **GPIO:** configure the desired I/O as output, input or analog in the GPIOx\_MODER register.
- **Peripheral’s alternate function:**  
 For the ADC and DAC, configure the desired I/O as analog in the GPIOx\_MODER register.  
 For other peripherals:
  - Configure the desired I/O as an alternate function in the GPIOx\_MODER register
  - Select the type, pull-up/pull-down and output speed via the GPIOx\_OTYPER, GPIOx\_PUPDR and GPIOx\_OSPEEDER registers, respectively
  - Connect the I/O to the desired AFx in the GPIOx\_AFRL or GPIOx\_AFRH register
- **EVENTOUT:** you can configure the I/O pin used to output the Cortex-M3 EVENTOUT signal by connecting it to AF15

*Note:* **EVENTOUT** is not mapped onto the following I/O pins: PH0, PH1 and PH2.

Please refer to the “Alternate function mapping” table in the STM32L15xxx datasheets for the detailed mapping of the system and peripherals’ alternate function I/O pins.

**Figure 15. Selecting an alternate function**

### 5.3.3 I/O port control registers

Each of the GPIOs has four 32-bit memory-mapped control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR) to configure up to 16 I/Os. The GPIOx\_MODER register is used to select the I/O direction (input, output, AF, analog). The GPIOx\_OTYPER and GPIOx\_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed (the I/O speed pins are directly connected to the corresponding GPIOx\_OSPEEDR register bits whatever the I/O direction). The GPIOx\_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 5.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx\_IDR and GPIOx\_ODR). GPIOx\_ODR stores the data to be output, it is read/write

accessible. The data input through the I/O are stored into the input data register (GPIOx\_IDR), a read-only register.

See [Section 5.4.5: GPIO port input data register \(GPIOx\\_IDR\) \(x = A..E and H\)](#) and [Section 5.4.6: GPIO port output data register \(GPIOx\\_ODR\) \(x = A..E and H\)](#) for the register descriptions.

### 5.3.5 I/O data bitwise handling

The bit set reset register (GPIOx\_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx\_ODR). The bit set reset register has twice the size of GPIOx\_ODR.

To each bit in GPIOx\_ODR, correspond two control bits in GPIOx\_BSRR: BSRR(i) and BSRR(i+SIZE). When written to 1, bit BSRR(i) **sets** the corresponding ODR(i) bit. When written to 1, bit BSRR(i+SIZE) **resets** the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx\_BSRR does not have any effect on the corresponding bit in GPIOx\_ODR. If there is an attempt to both set and reset a bit in GPIOx\_BSRR, the set action takes priority.

Using the GPIOx\_BSRR register to change the values of individual bits in GPIOx\_ODR is a “one-shot” effect that does not lock the GPIOx\_ODR bits. The GPIOx\_ODR bits can always be accessed directly. The GPIOx\_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx\_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

### 5.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx\_LCKR register. The frozen registers are GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH.

To write the GPIOx\_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next reset. Each GPIOx\_LCKR bit freezes the corresponding bit in the control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH).

The LOCK sequence (refer to [Section 5.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A..E and H\)](#)) can only be performed using a word (32-bit long) access to the GPIOx\_LCKR register due to the fact that GPIOx\_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details please refer to LCKR register description in [Section 5.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A..E and H\)](#).

### 5.3.7 I/O alternate function input/output

Two registers are provided to select one out of the sixteen alternate function inputs/outputs available for each I/O. With these registers, you can connect an alternate function to some other pin as required by your application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx\_AFRL and GPIOx\_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of one I/O.

To know which functions are multiplexed on each GPIO pin, refer to the STM32L15xxx datasheets.

*Note: The application is allowed to select one of the possible peripheral functions for each I/O at a time.*

### 5.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode, refer to [Section 7.2: External interrupt/event controller \(EXTI\)](#) and [Section 7.2.3: Wakeup event management](#).

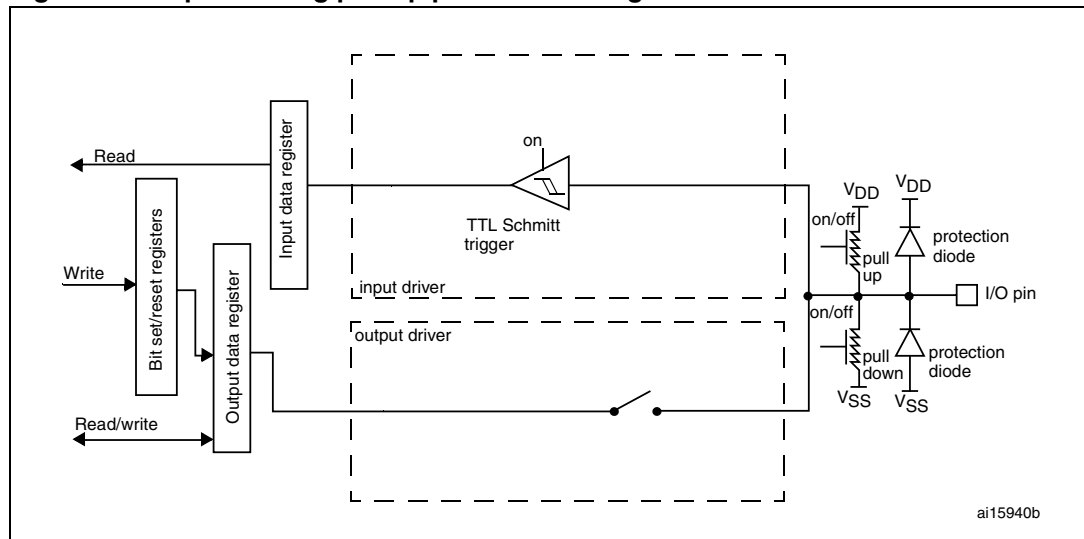

### 5.3.9 Input configuration

When the I/O port is programmed as Input:

- the output buffer is disabled
- the Schmitt trigger input is activated
- the pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O State

*Figure 16* shows the input configuration of the I/O port bit.

**Figure 16. Input floating/pull up/pull down configurations**

### 5.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value in Push-pull mode

Figure 17 shows the output configuration of the I/O port bit.

Figure 17. Output configuration

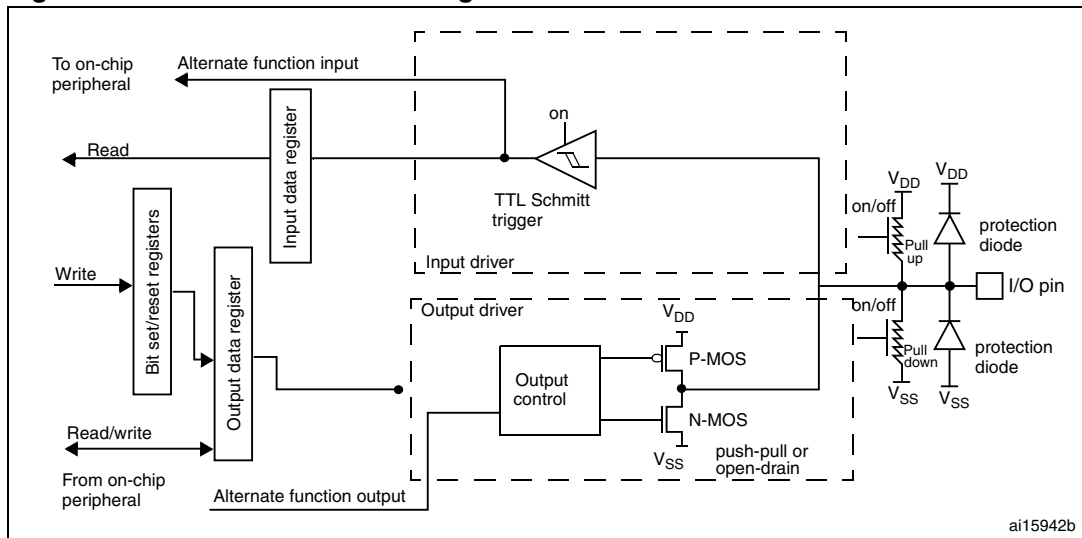

### 5.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer is turned on in open-drain or push-pull configuration
- The output buffer is driven by the signal coming from the peripheral (alternate function out)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last value written in push-pull mode

Figure 18 shows the Alternate function configuration of the I/O port bit.

**Figure 18. Alternate function configuration**

### 5.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled
- Read access to the input data register gets the value “0”

Figure 19 shows the high-impedance, analog-input configuration of the I/O port bit.

**Figure 19. High impedance-analog configuration**

### 5.3.13 Using the OSC32\_IN/OSC32\_OUT pins as GPIO PC14/PC15 port pins

The LSE oscillator pins OSC32\_IN and OSC32\_OUT can be used as general-purpose PC14 and PC15 I/Os, respectively, when the LSE oscillator is off (after reset, the LSE oscillator is off ). The PC14 and PC15 I/Os are only configured as OSC32\_IN and OSC32\_OUT LSE oscillator pins when the LSE oscillator is ON ( by setting the LSEON bit in the RCC\_CSR register). The LSE has priority over the GPIO function.

*Note:* 1 The PC14/PC15 GPIO functionality is lost when the V<sub>CORE</sub> domain is powered off (by the device entering the standby mode) . In this case the I/Os are set in analog input mode.

### 5.3.14 Using the OSC\_IN/OSC\_OUT pins as GPIO PH0/PH1 port pins

The HSE oscillator pins OSC\_IN/OSC\_OUT can be used as general-purpose PH0/PH1 I/Os, respectively, when the HSE oscillator is off. ( after reset, the HSE oscillator is off ). The PH0/PH1 I/Os are only configured as OSC\_IN/OSC\_OUT HSE oscillator pins when the HSE oscillator is ON ( by setting the HSEON bit in the RCC\_CR register). The HSE has priority over the GPIO function.

### 5.3.15 Selection of RTC\_AF1 alternate functions

The STM32L15xxx features:

- Two GPIO pins, which can be used as wakeup pins (WKUP1 and WKUP3).
- One GPIO pin, which can be used as a wakeup pin (WKUP2), for the detection of a tamper or time-stamp event, or to output RTC AFO\_ALARM or AFO\_CALIB.

The RTC\_AF1 pin (PC13) can be used for the following purposes:

- Wakeup pin 2 (WKUP2): this feature is enabled by setting the EWUP2 in the PWR\_CSR register.
- RTC AFO\_ALARM output: this output can be RTC Alarm A, RTC Alarm B or RTC Wakeup depending on the OSEL[1:0] bits in the RTC\_CR register.
- RTC AFO\_CALIB output: this feature is enabled by setting the COE[23] bit in the RTC\_CR register.
- RTC AFI\_TAMPER1: Tamper event detection
- Time-stamp event detection

The selection of the RTC AFO\_ALARM output is performed through the RTC\_TAFCR register as follows: ALARMOUTTYPE is used to select whether the RTC AFO\_ALARM output is configured in push-pull or open-drain mode.

The output mechanism follows the priority order shown in [Table 20](#).

**Table 20. RTC\_AF1 pin <sup>(1)</sup>**

Pin configuration and function	AFO_ALARM enabled	AFO_CALIB enabled	Tamper enabled	Time-stamp enabled	EWUP2 enabled	ALARMOUTTYPE AFO_ALARM configuration
Alarm out output OD	1	0	Don't care	Don't care	Don't care	0
Alarm out output PP	1	0	Don't care	Don't care	Don't care	1

Table 20. RTC\_AF1 pin (continued)<sup>(1)</sup>

Pin configuration and function	AFO_ALARM enabled	AFO_CALIB enabled	Tamper enabled	Time-stamp enabled	EWUP2 enabled	ALARMOUTTYPE AFO_ALARM configuration
Calibration out output PP	0	1	Don't care	Don't care	Don't care	Don't care
TAMPER input floating	0	0	1	0	Don't care	Don't care
TIMESTAMP and TAMPER input floating	0	0	1	1	Don't care	Don't care
TIMESTAMP input floating	0	0	0	1	Don't care	Don't care
Wakeup Pin 2	0	0	0	0	1	Don't care
Standard GPIO	0	0	0	0	0	Don't care

1. OD: open drain; PP: push-pull.

## 5.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to [Table 21](#).

The peripheral registers have to be accessed by words (32-bit).

### 5.4.1 GPIO port mode register (GPIOx\_MODER) (x = A..E and H)

Address offset: 0x00

Reset values:

- 0xA800 0000 for port A
- 0x0000 0280 for port B
- 0x0000 0000 for other ports

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODER15[1:0]		MODER14[1:0]		MODER13[1:0]		MODER12[1:0]		MODER11[1:0]		MODER10[1:0]		MODER9[1:0]		MODER8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODER7[1:0]		MODER6[1:0]		MODER5[1:0]		MODER4[1:0]		MODER3[1:0]		MODER2[1:0]		MODER1[1:0]		MODER0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 2y:2y+1 **MODERy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O direction mode.

00: Input (reset state)

01: General purpose output mode

10: Alternate function mode

11: Analog mode

### 5.4.2 GPIO port output type register (GPIOx\_OTYPER) (x = A..E and H)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OT15	OT14	OT13	OT12	OT11	OT10	OT9	OT8	OT7	OT6	OT5	OT4	OT3	OT2	OT1	OT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, always read as 0.

Bits 15:0 **OTy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the output type of the I/O port.

0: Output push-pull (reset state)

1: Output open-drain

### 5.4.3 GPIO port output speed register (GPIOx\_OSPEEDR) (x = A..E and H)

Address offset: 0x08

Reset values:

- 0x0000 00C0 for port B
- 0x0000 0000 for other ports

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEEDR15[1:0]		OSPEEDR14[1:0]		OSPEEDR13[1:0]		OSPEEDR12[1:0]		OSPEEDR11[1:0]		OSPEEDR10[1:0]		OSPEEDR9[1:0]		OSPEEDR8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OSPEEDR7[1:0]		OSPEEDR6[1:0]		OSPEEDR5[1:0]		OSPEEDR4[1:0]		OSPEEDR3[1:0]		OSPEEDR2[1:0]		OSPEEDR1[1:0]		OSPEEDR0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 2y:2y+1 **OSPEEDRy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O output speed.

00: 400 kHz Very low speed

01: 2 MHz Low speed

10: 10 MHz Medium speed

11: 40 MHz High speed on 50 pF (50 MHz output max speed on 30 pF)

### 5.4.4 GPIO port pull-up/pull-down register (GPIOx\_PUPDR) (x = A..E and H)

Address offset: 0x0C

Reset values:

- 0x6400 0000 for port A
- 0x0000 0100 for port B
- 0x0000 0000 for other ports

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPDR15[1:0]		PUPDR14[1:0]		PUPDR13[1:0]		PUPDR12[1:0]		PUPDR11[1:0]		PUPDR10[1:0]		PUPDR9[1:0]		PUPDR8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

PUPDR7[1:0]		PUPDR6[1:0]		PUPDR5[1:0]		PUPDR4[1:0]		PUPDR3[1:0]		PUPDR2[1:0]		PUPDR1[1:0]		PUPDR0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 2y:2y+1 **PUPDRy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

### 5.4.5 GPIO port input data register (GPIOx\_IDR) (x = A..E and H)

Address offset: 0x10

Reset value: 0x0000 xxxx (where x means undefined)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR15	IDR14	IDR13	IDR12	IDR11	IDR10	IDR9	IDR8	IDR7	IDR6	IDR5	IDR4	IDR3	IDR2	IDR1	IDR0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, always read as 0.

Bits 15:0 **IDRy[15:0]**: Port input data (y = 0..15)

These bits are read-only and can be accessed in word mode only. They contain the input value of the corresponding I/O port.

### 5.4.6 GPIO port output data register (GPIOx\_ODR) (x = A..E and H)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ODR15	ODR14	ODR13	ODR12	ODR11	ODR10	ODR9	ODR8	ODR7	ODR6	ODR5	ODR4	ODR3	ODR2	ODR1	ODR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, always read as 0.

Bits 15:0 **ODRy[15:0]**: Port output data (y = 0..15)

These bits can be read and written by software.

*Note: For atomic bit set/reset, the ODR bits can be individually set and reset by writing to the GPIOx\_BSRR register (x = A..E and H).*

### 5.4.7 GPIO port bit set/reset register (GPIOx\_BSRR) (x = A..E and H)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy**: Port x reset bit y (y = 0..15)

These bits are write-only and can be accessed in word, half-word or byte mode. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Resets the corresponding ODRx bit

*Note: If both BSx and BRx are set, BSx has priority.*

Bits 15:0 **BSy**: Port x set bit y (y = 0..15)

These bits are write-only and can be accessed in word, half-word or byte mode. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Sets the corresponding ODRx bit

### 5.4.8 GPIO port configuration lock register (GPIOx\_LCKR) (x = A..E and H)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next reset.

*Note: A specific write sequence is used to write to the GPIOx\_LCKR register. Only word access (32-bit long) is allowed during this write sequence.*

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

Access: 32-bit word only, read/write register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved

Bit 16 **LCKK[16]**: Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx\_LCKR register is locked until an MCU reset occurs.

LOCK key write sequence:

WR LCKR[16] = '1' + LCKR[15:0]

WR LCKR[16] = '0' + LCKR[15:0]

WR LCKR[16] = '1' + LCKR[15:0]

RD LCKR

RD LCKR[16] = '1' (this read operation is optional but it confirms that the lock is active)

*Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.*

*Any error in the lock sequence aborts the lock.*

*After the first lock sequence on any bit of the port, any read access on the LCKK bit will return '1' until the next CPU reset.*

Bits 15:0 **LCKy**: Port x lock bit y (y= 0..15)

These bits are read/write but can only be written when the LCKK bit is '0'.

0: Port configuration not locked

1: Port configuration locked

### 5.4.9 GPIO alternate function low register (GPIOx\_AFRL) (x = A..E and H)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to [Table 1: Register boundary addresses](#) for the register boundary addresses. The following tables give the GPIO register map and the reset values.

## 6 System configuration controller (SYSCFG) and routing interface (RI)

### 6.1 SYSCFG and RI introduction

The system configuration controller is mainly used to remap the memory accessible in the code area, and manage the external interrupt line connection to the GPIOs.

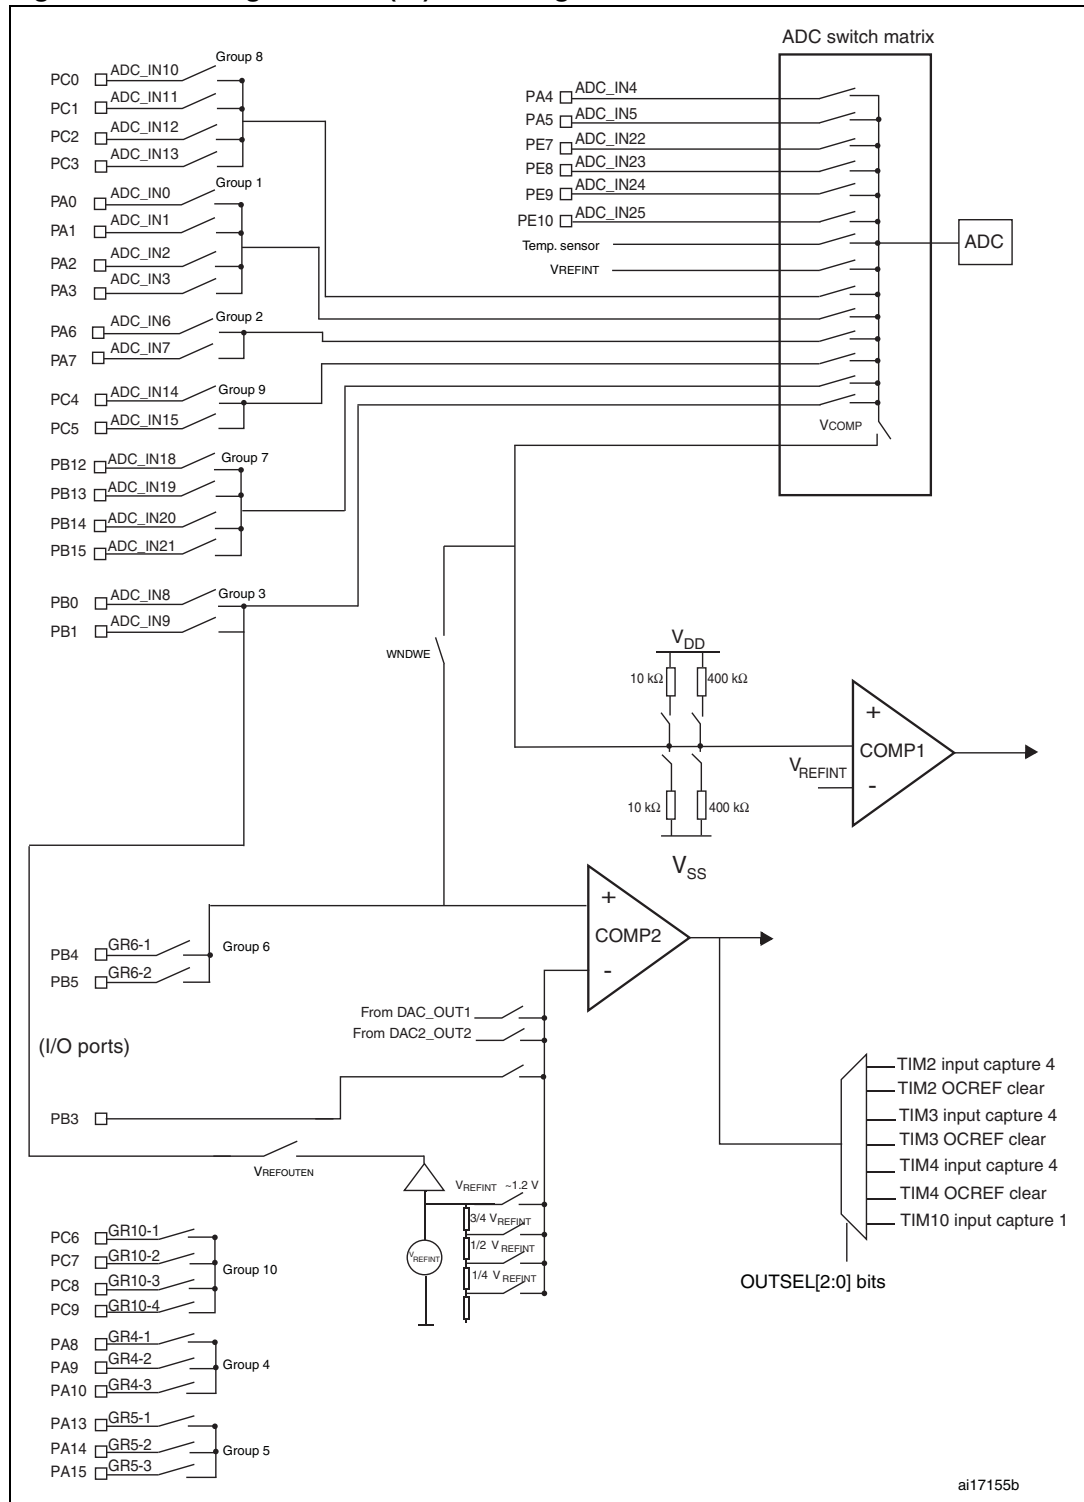

The routing interface provides high flexibility by allowing the software routing of I/Os toward the input captures of the STM32L15xxx's three high-end timers (TIM2, TIM3 and TIM4). The STM32L15xxx's ADC has an analog input matrix that is usually managed by a specific ADC interface. With the routing interface, it is possible to connect several I/O analog pins to a given channel of the ADC matrix by managing the analog switches of each I/O.

### 6.2 RI main features

- TIM2/TIM3/TIM4's input captures 1,2,3 and four routing selections from selectable I/Os
- Routing of internal reference voltage  $V_{REFINT}$  to selectable I/Os for all packages
- 24 external I/Os + 2 internal nodes (internal reference voltage + temperature sensor) can be used for data acquisition purposes in conjunction with the ADC interface
- Input and output routing of COMP1 and COMP2

*Note:* The RI registers can be accessed only when the comparator interface clock is enabled by setting the COMPEN bit in the RCC\_APB1ENR register. Refer to [Section 4.3.10 on page 97](#).

Figure 20. Routing interface (RI) block diagram

Note: The internal reference voltage and temperature sensor cannot be used as COMP1 non-inverting input.

## 6.3 RI functional description

### 6.3.1 Special I/O configuration

Two matrices of switches control the routing of I/Os toward analog blocks (that is the ADC or the comparator): I/O switches and ADC switches (refer to [Figure 20: Routing interface \(RI\) block diagram](#)).

- When I/Os are used for analog purposes other than data acquisition, the I/O and ADC switch matrices have to be controlled by the RI\_ASCRx and RI\_ASCRx registers. These registers are then used to close or open switches by software: closing switches sets the corresponding bits whereas opening switches clears them.
- When I/Os are used as ADC inputs for data acquisition purposes, the I/O and ADC switch matrices are directly controlled by the ADC interface. The corresponding bits in the RI\_ASCRx and RI\_ASCRx registers must be kept cleared (switches open).

Up to 6 I/Os are connected directly and independently to the ADC through the pad resistor: these fast channels are capable of fast acquisition (1 megasample/s at the maximum ADC acquisition time). Other ADC channels do not exceed 800 kilosamples/s.

When the I/Os are programmed in input mode by standard I/O port registers, the Schmitt trigger and the hysteresis are enabled by default. In this mode, the RI\_ASCRx and RI\_HYSCR registers can be used to simultaneously close the corresponding I/O analog switch and disable the Schmitt trigger hysteresis. It is therefore possible to read the corresponding port with a trigger level of  $V_{DDIO}/2$ .

Only 6 groups (18 I/Os) are multiplexed to the ADC by the I/O analog switches. With the 8 or 6 fast channels, this makes 24 I/Os available for data acquisition and COMP1 comparison versus  $V_{REFINT}$ .

*Note:* For all I/Os used as comparator inputs, the I/O port configuration must be kept in analog mode.

[Table 22](#) shows the grouping of I/Os, the control register bits used to configure them as analog inputs or outputs (irrespective of standard I/O port programming), and the associated ADC channel number.

**Table 22. I/O groups and selection**

Group numbering	GPIO port	Analog ADC channel	I/O + ADC analog switch	I/O functions	
Group 1	GR1-1	PA0	CH0	RI_ASCRx->CH0	COMP1_INP
	GR1-2	PA1	CH1	RI_ASCRx->CH1

### 6.3.2 Input capture routing

By default (at reset), the four input captures of the three general-purpose timers (TIM2, TIM3, TIM4) are connected to the I/O port specified in the STM32L15xxx datasheet's "pin descriptions" table.

The I/O routing can be changed by programming register RI\_ICR as indicated below:

- The input capture 1 of TIM2, TIM3 and TIM4 can be rerouted from any I/O by configuring the IC1IOS[3:0] bits in RI\_ICR.
- The input capture 2 of TIM2, TIM3 and TIM4 can be rerouted from any I/O by configuring the IC2IOS[3:0] bits in RI\_ICR.
- The input capture 3 of TIM2, TIM3 and TIM4 can be rerouted from any I/O by configuring the IC3IOS[3:0] bits in RI\_ICR.
- The input capture 4 of TIM2, TIM3 and TIM4 can be rerouted from any I/O by configuring the IC4IOS[3:0] bits in RI\_ICR.

Refer to the following table for I/O routing to the input capture timers.

This capability can be applied on only one out of the three timers at a time by configuring TIM[1:0] in RI\_ICR. When TIM[1:0]= 00 none of the three timers are affected by the I/O routing: the defaults connections are enabled.

Moreover, when a timer is selected, I/O routing can be enabled for one or more input captures by configuring the IC1, IC2, IC3 and IC4 bits in RI\_ICR.

Refer to [Table 23](#) for the I/O correspondence and to [Table 24](#) for the timer selection.

**Table 23. Input capture mapping**

1111	PE12 / PE13 / PE14 / PE15

*Note:* 1 The I/O should be configured in alternate function mode (AF14).

**Table 24. Timer selection**

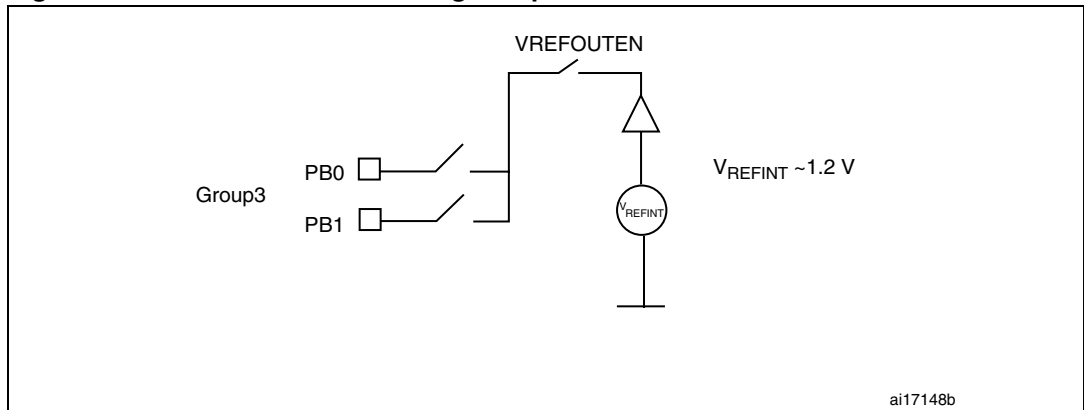

TIM[1:0]	Selected timer
00	No timer selected, default routing on all timers
01	TIM2 selected
10	TIM3 selected
11	TIM4 selected

**Table 25. Input capture selection**

IC4 / IC3 / IC2 / IC1	Selected input capture
0	IC deselected, default routing on the input capture (AF)
1	Input capture routing follows <a href="#">Table 24</a>

### 6.3.3 Reference voltage routing

**Figure 21. Internal reference voltage output**

The  $V_{REFINT}$  output can be routed to any I/O in group 3 by following this procedure:

1. Set the VREFOUTEN bit in COMP\_CSR.
2. Close the analog switch of all I/Os in group 3 by setting CH8 or CH9 in RI\_ASCR1.

## 6.4 RI registers

The peripheral registers have to be accessed by words (32-bit).

### 6.4.1 RI input capture register (RI\_ICR)

The RI\_ICR register is used to select the routing of 4 full ports to the input captures of TIM2, TIM3 and TIM4.

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept cleared.

Bit 21 **IC4**: This bit is set and cleared by software to select the standard AF or the large routing capability on the input capture 4 of the timer selected by TIM[1:0] (bits 17:16).

0: AF on IC4

1: Multiple port routing capability according to IC4IOS[3:0] (bits 15:12)

Bit 20 **IC3**: This bit is set and cleared by software to select the standard AF or the large routing capability on the input capture 3 of the timer selected by TIM[1:0] (bits 17:16).

0: AF on IC3

1: Multiple port routing capability according to IC3IOS[3:0] (bits 11:8)

Bit 19 **IC2**: This bit is set and cleared by software to select the standard AF or the large routing capability on the input capture 2 of the timer selected by TIM[1:0] (bits 17:16).

0: AF on IC2

1: Multiple port routing capability according to IC2IOS[3:0] (bits 7:4)

Bit 18 **IC1**: This bit is set and cleared by software to select the standard AF or the large routing capability on the input capture 2 of the timer selected by TIM[1:0] (bits 17:16).

0: AF on IC1

1: Multiple port routing capability according to IC1IOS[3:0] (bits 3:0)

Bits 17:16 **TIM[1:0]**: Timer select bits

These bits are set and cleared by software. They are used to select one out of three timers or none.

00: non timer selected

01: TIM2 selected

10: TIM3 selected

11: TIM4 selected

Bits 15:12 **IC4IOS[3:0]**: Input capture 4 select bits

These bits are set and cleared by software. They select the input port to be routed to the IC4 of the selected timer (see bits 16:17).

0000: PA3	1000: PD3
0001: PA7	1001: PD7

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
CH15	CH14	CH13	CH12	CH11	CH10	CH9	CH8	CH7	CH6	CH5	CH4	CH3	CH2	CH1	CH0						
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw						

Bit 31 **SCM**: Switch control mode

This bit is set and cleared by software to control the analog ADC switches according to the state of the analog I/O switches controlled by bits [25:18] and [15:0].

- 0: ADC analog switches open or controlled by the ADC interface
- 1: ADC analog switches closed if the corresponding I/O switch is also closed

Bits 30:27 Reserved

Bit 26 **VCOMP**: ADC analog switch selection for internal node to comparator 1

This bit is set and cleared by software to control the VCOMP ADC analog switch. See [Figure 50 on page 236](#).

- 0: Analog switch open
- 1: Analog switch closed

Bits 25:22 **CH[25:22]**: Analog I/O switch control of channels CH[25:22]

These bits are set and cleared by software to control the analog switches. If the I/O is used as an ADC input, the switch must be left open to allow the ADC to control it.

- 0: Analog switch open
- 1: Analog switch closed

Bits 21:18 **CH[21:18]** Analog switch control

These bits are set and cleared by software to control the analog switches.

- 0: Analog switch open
- 1: Analog switch closed

Bits 17:16 Reserved

Bits 15:0 **CH[15:0]**: Analog I/O switch control of channels CH[15:0]

These bits are set and cleared by software to control the analog switches. If the I/O is used as an ADC input, the switch must be left open to allow the ADC to control it.

- 0: Analog switch open
- 1: Analog switch closed

- Note:*
- 1 The ADC\_IN16 and ADC\_IN17 channels are internal and controlled only by the ADC interface for data acquisition purposes.
  - 2 The ADC\_IN4, ADC\_IN5, ADC\_IN22, ADC\_IN23, ADC\_IN24 and ADC\_IN25 channels are directly connected to the ADC through a resistor, no need to close external I/O analog switches.
  - 3 When the SCM bit is low, the CH bits are used to connect groups of I/Os together by analog switches, independently of the ADC.
  - 4 When the SCM bit is high, the CH bits are used to connect several I/Os together through the ADC switch matrix in order to allow a possible wakeup by COMP1 if the VCOMP bit is high.

### 6.4.3 RI analog switch control register 2 (RI\_ASCR2)

The RI\_ASCR2 register is used to configure the analog switches of groups of I/Os not linked to the ADC. In this way, predefined groups of I/Os can be connected together.

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept cleared.

Bit 11:0 **GRx-x**: GRx-x analog switch control

These bits are set and cleared by software to control the analog switches independently. Refer to [Table 22: I/O groups and selection on page 128](#) from the ADC interface.

- 0: Analog switch open
- 1: Analog switch closed

### 6.4.4 RI hysteresis control register (RI\_HYSCR1)

The RI\_HYSCR1 register is used to enable/disable the hysteresis of the input Schmitt trigger of ports A and B.

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **PB[15:0]**: Port B hysteresis control on/off

These bits are set and cleared by software to control the Schmitt trigger hysteresis of the Port B[15:0].

0: Hysteresis on

1: Hysteresis off

Bits 15:0 **PA[15:0]**: Port A hysteresis control on/off

These bits are set and cleared by software to control the Schmitt trigger hysteresis of the Port A[15:0].

0: Hysteresis on

1: Hysteresis off

### 6.4.5 RI Hysteresis control register (RI\_HYSCR2)

RI\_HYSCR2 register allows to enable/disable hysteresis of input Schmitt trigger of ports C and D.

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **PD[15:0]**: Port D hysteresis control on/off

These bits are set and cleared by software to control the Schmitt trigger hysteresis of the Port D[15:0].

0: Hysteresis on

1: Hysteresis off

Bits 15:0 **PC[15:0]**: Port C hysteresis control on/off

These bits are set and cleared by software to control the Schmitt trigger hysteresis of the Port C[15:0].

- 0: Hysteresis on
- 1: Hysteresis off

### 6.4.6 RI Hysteresis control register (RI\_HYSCR3)

The RI\_HYSCR3 register is used to enable/disable the hysteresis of the input Schmitt trigger of the entire port E.

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 27:22 Reserved, must be kept cleared.

Bits 15:0 **PE[15:0]**: Port E hysteresis control on/off

These bits are set and cleared by software to control the Schmitt trigger hysteresis of the Port E[15:0].

- 0: Hysteresis on
- 1: Hysteresis off

### 6.4.7 Analog switch mode register (RI\_ASMR1)

The RI\_ASMR1 register is used to select if analog switches of port A are to be controlled by the timer OC or through the ADC interface or RI\_ASCRx registers.

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PA[15:0]: Port A analog switch mode selection**

These bits are set and cleared by software to select the mode of controlling the analog switches for Port A.

- 0: ADC interface or RI\_ASCRx controlled
- 1: Timer controlled

### 6.4.8 Channel mask register (RI\_CM1)

RI\_CM1 is used to mask a port A channel designated as a timer input capture (after acquisition completion to avoid triggering multiple detections).

Address offset: 0x24

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PA[15:0]: Port A channel masking**

These bits are set and cleared by software to mask the ZI input of Port A.

- 0: Masked
- 1: Not masked

### 6.4.9 Channel identification for capture register (RI\_CICR1)

The RI\_CICR1 register is used when analog switches are controlled by a timer OC. RI\_CICR1 allows a channel to be identified for timer input capture.

Address offset: 0x28

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PA[15:0]**: Port A channel identification for capture

These bits are set and cleared by software to identify the sampling capacitor I/Os on Port A.

- 0: Channel I/O
- 1: Sampling capacitor I/O

### 6.4.10 Analog switch mode register (RI\_ASMR2)

The RI\_ASMR2 register is used to select if analog switches of port B are to be controlled by the timer OC or through the ADC interface or RI\_ASCRx registers.

Address offset: 0x2C

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PB[15:0]**: Port B analog switch mode selection

These bits are set and cleared by software to select the mode of controlling the analog switches for Port B.

- 0: ADC interface or RI\_ASCRx controlled
- 1: Timer controlled

### 6.4.11 Channel mask register (RI\_CMR2)

RI\_CMR2 is used to mask a por B channel designated as a timer input capture (after acquisition completion to avoid triggering multiple detections)

Address offset: 0x30

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PB[15:0]**: *Port B channel masking*

These bits are set and cleared by software to mask ZI input of Port B.

0: Masked

1: Not masked

### 6.4.12 Channel identification for capture register (RI\_CICR2)

The RI\_CICR2 register is used when analog switches are controlled by a timer OC. RI\_CICR2 allows a port B channel to be identified for timer input capture.

Address offset: 0x34

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PB[15:0]**: *Port B channel identification for capture*

These bits are set and cleared by software to identify the sampling capacitor I/Os on Port B.

0: Channel I/O

1: Sampling capacitor I/O

### 6.4.13 Analog switch mode register (RI\_ASMR3)

The RI\_ASMR3 register is used to select if analog switches of port C are to be controlled by the timer OC or through the ADC interface or RI\_ASCRx registers.

Address offset: 0x38

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PC[15:0]: Port C analog switch mode selection**

These bits are set and cleared by software to select the mode of controlling the analog switches for Port C.

- 0: ADC interface or RI\_ASCRx controlled
- 1: Timer controlled

### 6.4.14 Channel mask register (RI\_CM3)

RI\_CM3 is used to mask a port C channel designated as a timer input capture (after acquisition completion to avoid triggering multiple detections)

Address offset: 0x3C

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PC[15:0]: Port C channel masking**

These bits are set and cleared by software to mask ZI input of Port C.

- 0: Masked
- 1: Not masked

### 6.4.15 Channel identification for capture register (RI\_CICR3)

The RI\_CICR3 register is used when analog switches are controlled by a timer OC. RI\_CICR3 allows a port C channel to be identified for timer input capture.

Address offset: 0x40

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **PC[15:0]**: Port C channel identification for capture

These bits are set and cleared by software to identify the sampling capacitor I/Os on Port C.

0: Channel I/O

1: Sampling capacitor I/O

### 6.4.16 RI register map

Table 26 summarizes the RI registers.

**Table 26. RI register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 6.5 SYSCFG registers

The peripheral registers have to be accessed by words (32-bit).

### 6.5.1 SYSCFG memory remap register (SYSCFG\_MEMRMP)

This register is used for specific configurations on memory remap:

- Two bits are used to configure the type of memory accessible at address 0x0000 0000. These bits are used to select the physical remap by software and so, bypass the BOOT pins.
- After reset these bits take the value selected by the BOOT pins.

*Note:* This register is not reset through the SYSCFGRST bit in the RCC\_APB2RSTR register.

Address offset: 0x00

Reset value: 0x0000 000X (X is the memory mode selected by the BOOT pins)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														MEM_MODE	
														rw	rw

Bits 31:2 Reserved

Bits 1:0 **MEM\_MODE**: Memory mapping selection

Set and cleared by software. This bit controls the memory’s internal mapping at address 0x0000 0000. After reset these bits take on the memory mapping selected by the BOOT pins.

- 00: Main Flash memory mapped at 0x0000 0000
- 01: System Flash memory mapped at 0x0000 0000
- 10: Reserved
- 11: SRAM mapped at 0x0000 0000

### 6.5.2 SYSCFG peripheral mode configuration register (SYSCFG\_PMC)

An internal pull-up resistor (1.5 kΩ) can be connected by software on the USB data + (DP) line. This internal pull-up resistor is enabled if the USB is not in power-down mode and if the USB\_PU bit is set.

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														USB_PU	
														rw	

Bits 31:1 Reserved

Bit 0 **USB\_PU** *USB pull-up enable on DP line*

Set and cleared by software. This bit controls the internal pull-up (1.5 kΩ) on the USB DP line.

0: no pull-up on the USB DP line (even if USB is not in power down mode)

1: internal pull-up is connected on USB DP line (only if USB is not in power down mode)

### 6.5.3 SYSCFG external interrupt configuration register 1 (SYSCFG\_EXTICR1)

Address offset: 0x08

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI3[3:0]				EXTI2[3:0]				EXTI1[3:0]				EXTI0[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 0 to 3)

These bits are written by software to select the source input for the EXTIx external interrupt.

0000: PA[x] pin

0001: PB[x] pin

0010: PC[x] pin

0011: PD[x] pin

0100: PE[x] pin

0101: PH[x] (only PH[2:0])

PH[3] is not used.

### 6.5.4 SYSCFG external interrupt configuration register 2 (SYSCFG\_EXTICR2)

Address offset: 0x0C

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI7[3:0]				EXTI6[3:0]				EXTI5[3:0]				EXTI4[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 4 to 7)

These bits are written by software to select the source input for the EXTIx external interrupt.

- 0000: PA[x] pin
- 0001: PB[x] pin
- 0010: PC[x] pin
- 0011: PD[x] pin
- 0100: PE[x] pin
- PH[7:4] are not used.

### 6.5.5 SYSCFG external interrupt configuration register 3 (SYSCFG\_EXTICR3)

Address offset: 0x10

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI11[3:0]				EXTI10[3:0]				EXTI9[3:0]				EXTI8[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 8 to 11)

These bits are written by software to select the source input for the EXTIx external interrupt.

- 0000: PA[x] pin
- 0001: PB[x] pin
- 0010: PC[x] pin
- 0011: PD[x] pin
- 0100: PE[x] pin
- PH[11:8] are not used.

### 6.5.6 SYSCFG external interrupt configuration register 4 (SYSCFG\_EXTICR4)

Address offset: 0x14

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI15[3:0]				EXTI14[3:0]				EXTI13[3:0]				EXTI12[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 12 to 15)

These bits are written by software to select the source input for the EXTIx external interrupt.

0000: PA[x] pin

0001: PB[x] pin

0010: PC[x] pin

0011: PD[x] pin

0100: PE[x] pin

PH[15:12] are not used.

### 6.5.7 SYSCFG register map

The following table gives the SYSCFG register map and the reset values.

**Table 27. SYSCFG register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x00	SYSCFG_MEMRMP Reset value	Reserved																										x	MEM_MODE	x			
0x04	SYSCFG_PMC Reset value	Reserved																										0	USB_PU	0			
0x08	SYSCFG_EXTICR1 Reset value	Reserved									EXTI3[3:0]				EXTI2[3:0]				EXTI1[3:0]				EXTI0[3:0]				0		0				
0x0C	SYSCFG_EXTICR2 Reset value	Reserved									EXTI7[3:0]				EXTI6[3:0]				EXTI5[3:0]				EXTI4[3:0]				0		0				
0x10	SYSCFG_EXTICR3 Reset value	Reserved									EXTI11[3:0]				EXTI10[3:0]				EXTI9[3:0]				EXTI8[3:0]				0		0

Refer to *Table: "Register boundary addresses"*.

# 7 Interrupts and events

This Section applies to the whole STM32L15xxx family, unless otherwise specified.

## 7.1 Nested vectored interrupt controller (NVIC)

### Features

- 45 maskable interrupt channels (not including the 16 interrupt lines of Cortex™-M3)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low-latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts including the core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming see Chapter 5 “Exceptions & Chap 8 Nested Vectored Interrupt Controller” in the ARM *Cortex™-M3 Technical Reference Manual*.

### 7.1.1 SysTick calibration value register

The SysTick calibration value is fixed to 4000, which gives a reference time base of 1 ms with the SysTick clock set to 4 MHz (max HCLK/8).

### 7.1.2 Interrupt and exception vectors

[Table 28](#) is the vector table for STM32L15xxx devices.

**Table 28. Vector table**

Position	Priority	Type of priority	Acronym	Description	Address
	-	-	-	Reserved	0x0000_0000
	-3	fixed	Reset	Reset	0x0000_0004
	-2	fixed	NMI_Handler	Non maskable interrupt. The RCC Clock Security System (CSS) is linked to the NMI vector.	0x0000_0008
	-1	fixed	HardFault_Handler	All class of fault	0x0000_000C
	0	settable	MemManage_Handler	Memory management	0x0000_0010
	1	settable	BusFault_Handler	Pre-fetch fault, memory access fault	0x0000_0014
	2	settable	UsageFault_Handler	Undefined instruction or illegal state	0x0000_0018
	-	-	-	Reserved	0x0000_001C - 0x0000_002B
	3	settable	SVC_Handler	System service call via SWI instruction	0x0000_002C

Table 28. Vector table (continued)

Position	Priority	Type of priority	Acronym	Description	Address
	4	settable	DebugMon_Handler	Debug Monitor	0x0000_0030
	-	-	-	Reserved	0x0000_0034
	5	settable	PendSV_Handler	Pendable request for system service	0x0000_0038
	6	settable	SysTick_Handler	System tick timer	0x0000_003C
0	7	settable	WWDG	Window Watchdog interrupt	0x0000_0040
1	8	settable	PVD	PVD through EXTI Line detection interrupt	0x0000_0044
2	9	settable	TAMPER_STAMP	Tamper and TimeStamp through EXTI line interrupts	0x0000_0048
3	10	settable	RTC_WKUP	RTC Wakeup through EXTI line interrupt	0x0000_004C
4	11	settable	FLASH	Flash global interrupt	0x0000_0050
5	12	settable	RCC	RCC global interrupt	0x0000_0054

42	49	settable	USB_FS_WKUP	USB Device FS Wakeup through EXTI line interrupt	0x0000_00E8
43	50	settable	TIM6	TIM6 global interrupt	0x0000_00EC
44	51	settable	TIM7	TIM7 global interrupt	0x0000_00F0

## 7.2 External interrupt/event controller (EXTI)

The external interrupt/event controller consists of up to 23 edge detectors for generating event/interrupt requests. Each input line can be independently configured to select the type (pulse or pending) and the corresponding trigger event (rising edge, falling edge or both). Each line can also be masked independently. A pending register maintains the status line of the interrupt requests.

### 7.2.1 Main features

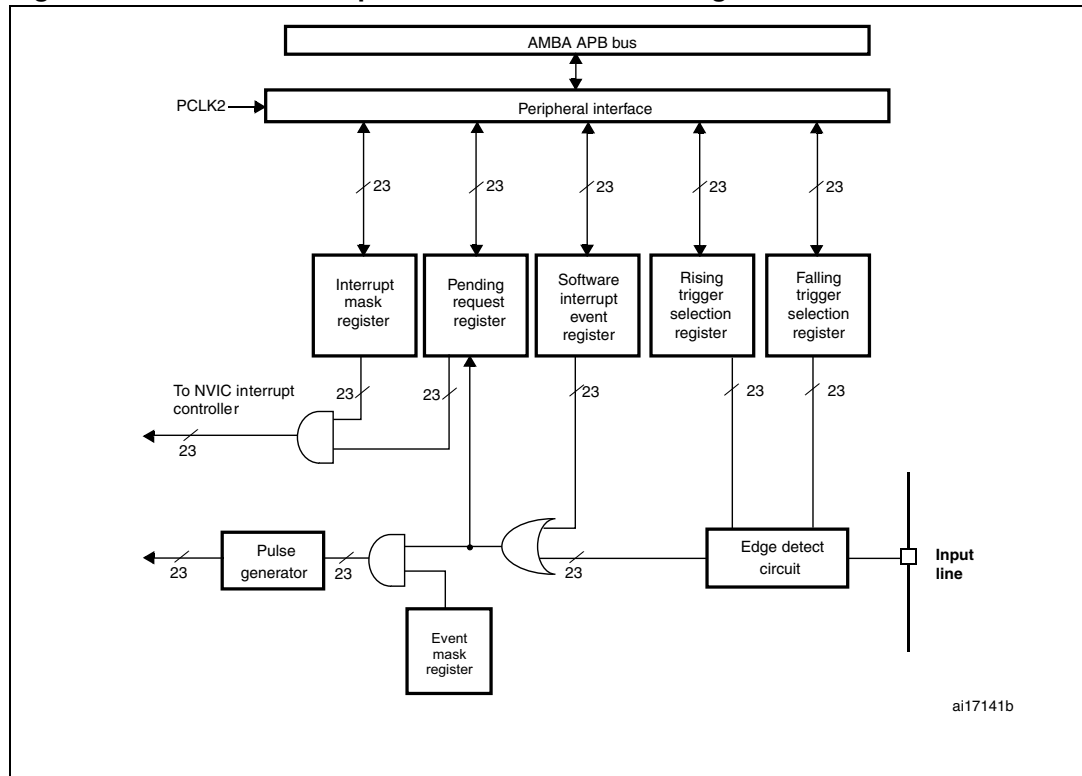

The main features of the EXTI controller are the following:

- Independent trigger and mask on each interrupt/event line
- Dedicated status bit for each interrupt line
- Generation of up to 23 software event/interrupt requests
- Detection of external signals with a pulse width lower than the APB2 clock period. Refer to the electrical characteristics section of the STM32L15xxx datasheet for details on this parameter.

## 7.2.2 Block diagram

The block diagram is shown in [Figure 22](#).

**Figure 22. External interrupt/event controller block diagram**

## 7.2.3 Wakeup event management

The STM32L15xxx is able to handle external or internal events in order to wake up the core (WFE). The wakeup event can be generated by either:

- enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex-M3 system control register. When the MCU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
- or configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

To use an external line as a wakeup event, refer to [Section 7.2.4: Functional description](#).

## 7.2.4 Functional description

To generate the interrupt, the interrupt line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the interrupt request by writing a '1' to the corresponding bit in the interrupt mask register. When the selected edge occurs on the external interrupt line, an interrupt request is generated. The pending bit corresponding to the interrupt line is also set. This request is reset by writing a '1' into the pending register.

To generate the event, the event line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the event request by writing a '1' to the corresponding bit in the event mask register. When the selected edge occurs on the event line, an event pulse is generated. The pending bit corresponding to the event line is not set

An interrupt/event request can also be generated by software by writing a '1' into the software interrupt/event register.

### Hardware interrupt selection

To configure the 23 lines as interrupt sources, use the following procedure:

- Configure the mask bits of the 23 Interrupt lines (EXTI\_IMR)
- Configure the Trigger Selection bits of the Interrupt lines (EXTI\_RTISR and EXTI\_FTISR)
- Configure the enable and mask bits that control the NVIC IRQ channel mapped to the external interrupt controller (EXTI) so that an interrupt coming from any one of the 23 lines can be correctly acknowledged.

### Hardware event selection

To configure the 23 lines as event sources, use the following procedure:

- Configure the mask bits of the 23 Event lines (EXTI\_EMR)
- Configure the Trigger Selection bits of the Event lines (EXTI\_RTISR and EXTI\_FTISR)

### Software interrupt/event selection

The 23 lines can be configured as software interrupt/event lines. The following is the procedure to generate a software interrupt.

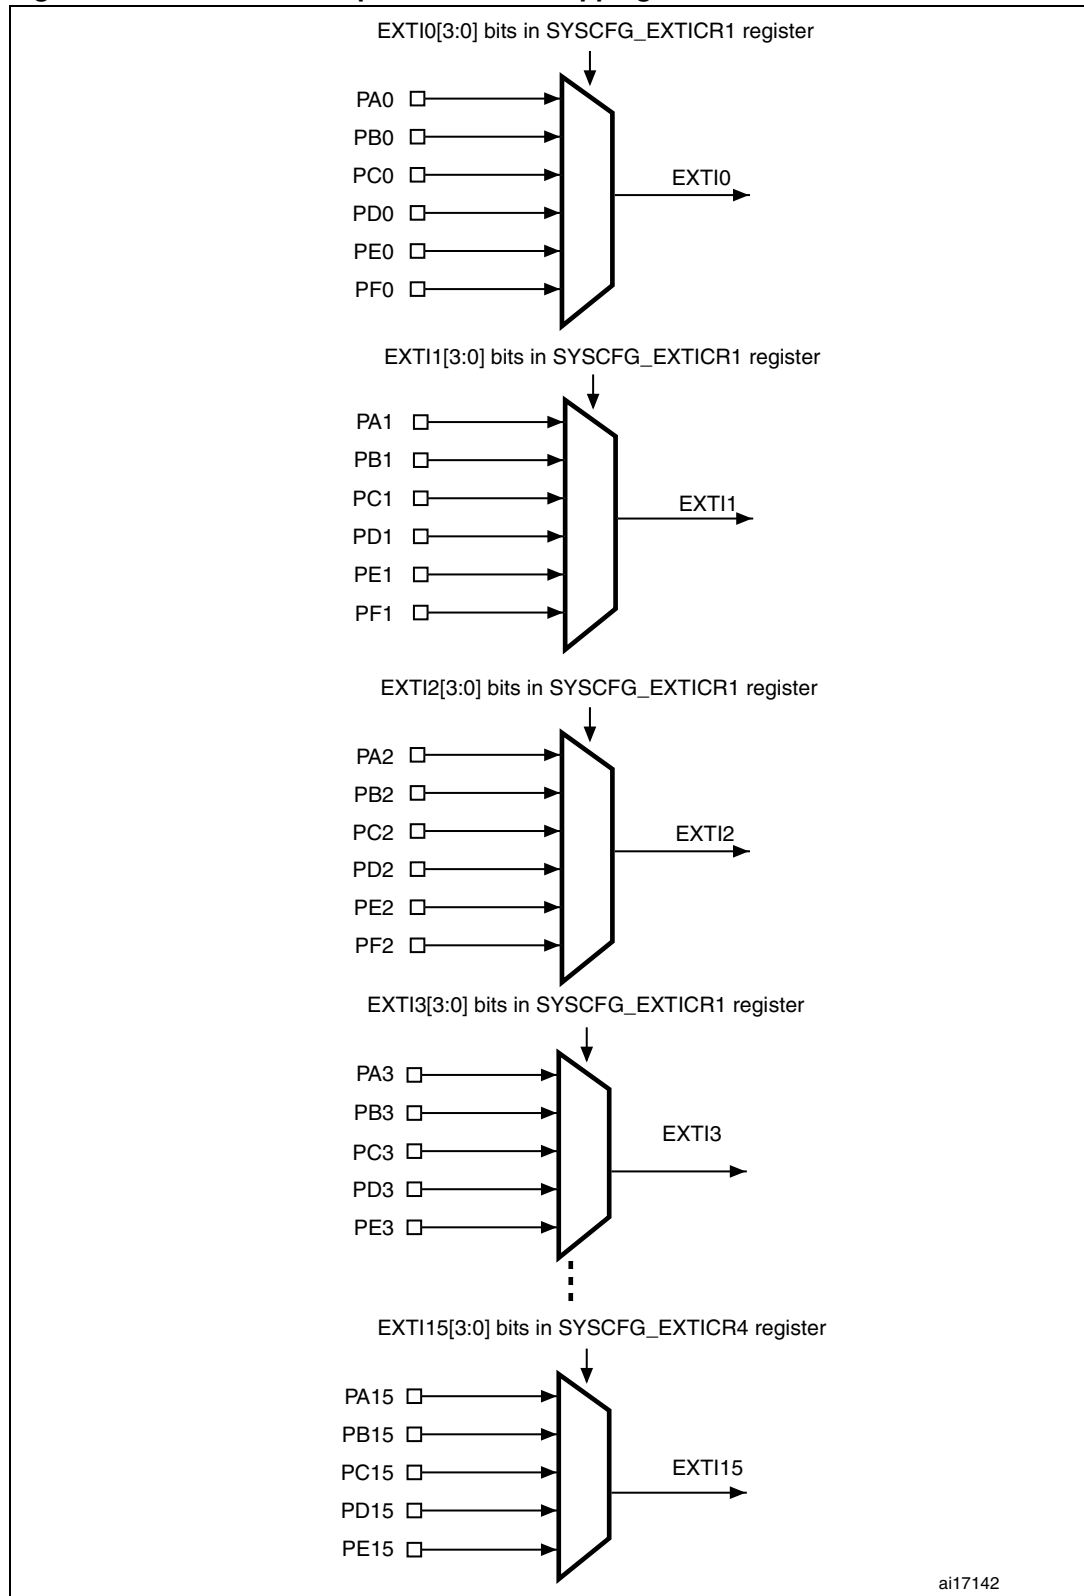

- Configure the mask bits of the 23 Interrupt/Event lines (EXTI\_IMR, EXTI\_EMR)
- Set the required bit in the software interrupt register (EXTI\_SWIER)

## 7.2.5 External interrupt/event line mapping

The 83 GPIOs are connected to the 16 external interrupt/event lines in the following manner:

Figure 23. External interrupt/event GPIO mapping

The six other EXTI lines are connected as follows:

- EXTI line 16 is connected to the PVD output
- EXTI line 17 is connected to the RTC Alarm event
- EXTI line 18 is connected to the USB Device FS wakeup event
- EXTI line 19 is connected to the RTC Tamper and TimeStamp events
- EXTI line 20 is connected to the RTC Wakeup event
- EXTI line 21 is connected to the Comparator 1 wakeup event and EXTI line 22 is connected to the Comparator 2 wakeup event

### 7.3 EXTI registers

Refer to [Section 1.1](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

#### 7.3.1 EXTI interrupt mask register (EXTI\_IMR)

Address offset: 0x00

Reset value: 0x0000 0000

Reserved									MR22	MR21	MR20	MR19	MR18	MR17	MR16
									rw	rw	rw	rw	rw	rw	rw
MR15	MR14	MR13	MR12	MR11	MR10	MR9	MR8	MR7	MR6	MR5	MR4	MR3	MR2	MR1	MR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:0 **MRx**: Interrupt mask on line x

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is not masked

#### 7.3.2 EXTI event mask register (EXTI\_EMR)

Address offset: 0x04

Reset value: 0x0000 0000

Reserved									MR22	MR21	MR20	MR19	MR18	MR17	MR16
									rw	rw	rw	rw	rw	rw	rw
MR15	MR14	MR13	MR12	MR11	MR10	MR9	MR8	MR7	MR6	MR5	MR4	MR3	MR2	MR1	MR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:0 **MRx**: Event mask on line x  
 0: Event request from Line x is masked  
 1: Event request from Line x is not masked

### 7.3.3 EXTI rising edge trigger selection register (EXTI\_RTSR)

Address offset: 0x08  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									TR22	TR21	TR20	TR19	TR18	TR17	TR16
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TR15	TR14	TR13	TR12	TR11	TR10	TR9	TR8	TR7	TR6	TR5	TR4	TR3	TR2	TR1	TR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:0 **TRx**: Rising edge trigger event configuration bit of line x  
 0: Rising edge trigger disabled (for Event and Interrupt) for input line x  
 1: Rising edge trigger enabled (for Event and Interrupt) for input line x

*Note:* The external wakeup lines are edge triggered, no glitch must be generated on these lines. If a rising edge on the external interrupt line occurs while writing to the EXTI\_RTISR register, the pending bit will not be set.  
 Rising and falling edge triggers can be set for the same interrupt line. In this configuration, both generate a trigger condition.

### 7.3.4 Falling edge trigger selection register (EXTI\_FTSR)

Address offset: 0x0C  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									TR22	TR21	TR20	TR19	TR18	TR17	TR16
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TR15	TR14	TR13	TR12	TR11	TR10	TR9	TR8	TR7	TR6	TR5	TR4	TR3	TR2	TR1	TR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:0 **TRx**: Falling edge trigger event configuration bit of line x  
 0: Falling edge trigger disabled (for Event and Interrupt) for input line x  
 1: Falling edge trigger enabled (for Event and Interrupt) for input line x

*Note:* The external wakeup lines are edge triggered, no glitch must be generated on these lines. If a falling edge on the external interrupt line occurs while writing to the EXTI\_FTSR register, the pending bit will not be set.

Rising and falling edge triggers can be set for the same interrupt line. In this configuration, both generate a trigger condition.

### 7.3.5 EXTI software interrupt event register (EXTI\_SWIER)

Address offset: 0x10  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									SWIER 22	SWIER 21	SWIER 20	SWIER 19	SWIER 18	SWIER 17	SWIER 16
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWIER 15	SWIER 14	SWIER 13	SWIER 12	SWIER 11	SWIER 10	SWIER 9	SWIER 8	SWIER 7	SWIER 6	SWIER 5	SWIER 4	SWIER 3	SWIER 2	SWIER 1	SWIER 0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:0 **SWIERx**: Software interrupt on line x  
 Writing a 1 to this bit when it is at 0 sets the corresponding pending bit in EXTI\_PR. If the interrupt is enabled on this line in EXTI\_IMR and EXTI\_EMR, an interrupt request is generated.  
 This bit is cleared by clearing the corresponding bit in EXTI\_PR (by writing a 1 to this bit).

### 7.3.6 EXTI pending register (EXTI\_PR)

Address offset: 0x14  
 Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									PR22	PR21	PR20	PR19	PR18	PR17	PR16
									rw	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PR15	PR14	PR13	PR12	PR11	PR10	PR9	PR8	PR7	PR6	PR5	PR4	PR3	PR2	PR1	PR0
rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:0 **PRx**: Pending bit

0: No trigger request occurred

1: The selected trigger request occurred

This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing it to 1 or by changing the sensitivity of the edge detector.

### 7.3.7 EXTI register map

The following table gives the EXTI register map and the reset values.

**Table 29. External interrupt/event controller register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x00	EXTI_IMR	Reserved									MR[22:0]																						
	Reset value										0   0																						
0x04	EXTI_EMR	Reserved									MR[22:0]																						
	Reset value										0   0																						
0x08	EXTI_RTSR	Reserved									TR[22:0]																						
	Reset value										0   0																						
0x0C	EXTI_FTSTR	Reserved									TR[22:0]																						
	Reset value										0   0																						
0x10	EXTI_SWIER	Reserved									SWIER[22:0]																						
	Reset value										0   0																						
0x14	EXTI_PR	Reserved									PR[22:0]																						
	Reset value										0   0																						

Refer to [Table 1 on page 32](#) for the register boundary addresses.

## 8 DMA controller (DMA)

### 8.1 DMA introduction

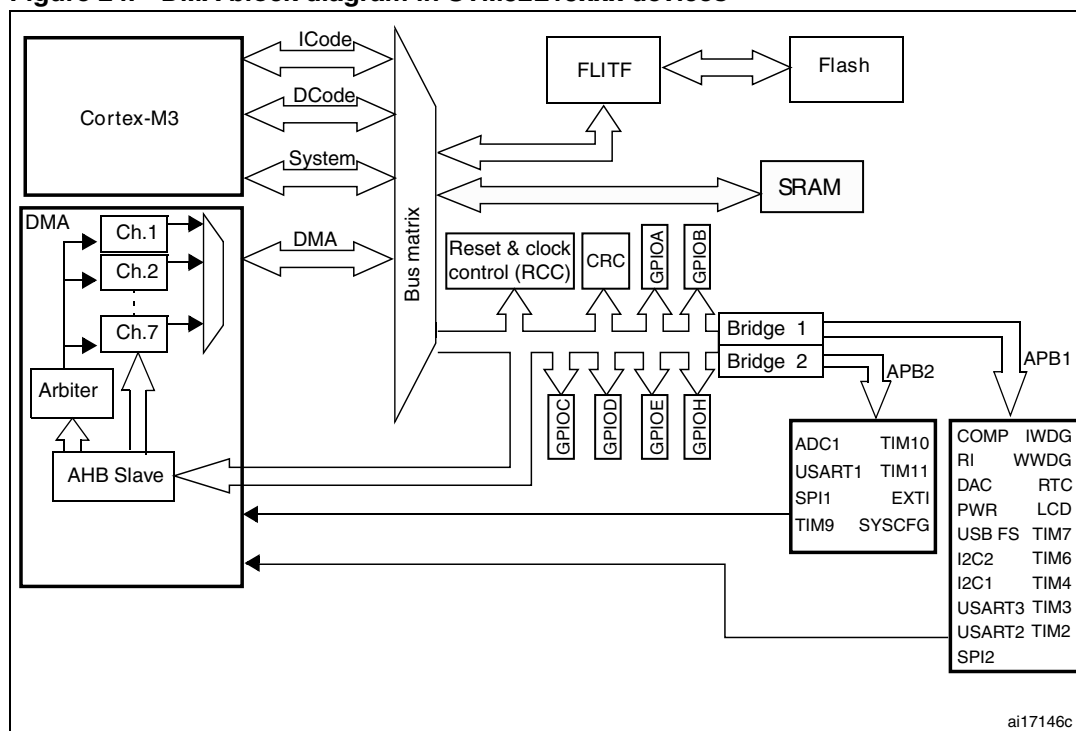

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory as well as memory to memory. Data can be quickly moved by DMA without any CPU actions. This keeps CPU resources free for other operations.

### 8.2 DMA main features

- Each of the channels is connected to dedicated hardware DMA requests, software trigger is also supported on each channel. This configuration is done by software.
- Priorities between requests from channels of one DMA are software programmable (4 levels consisting of *very high*, *high*, *medium*, *low*) or hardware in case of equality (request 1 has priority over request 2, etc.)
- Independent source and destination transfer size (byte, half word, word), emulating packing and unpacking. Source/destination addresses must be aligned on the data size.
- Support for circular buffer management
- 3 event flags (DMA Half Transfer, DMA Transfer complete and DMA Transfer Error) logically ORed together in a single interrupt request for each channel
- Memory-to-memory transfer
- Peripheral-to-memory and memory-to-peripheral, and peripheral-to-peripheral transfers
- Access to Flash, SRAM, APB1, APB2 and AHB peripherals as source and destination
- Programmable number of data to be transferred: up to 65536

The block diagram is shown in [Figure 24](#).

**Figure 24. DMA block diagram in STM32L15xxx devices**

## 8.3 DMA functional description

The DMA controller performs direct memory transfer by sharing the system bus with the Cortex™-M3 core. The DMA request may stop the CPU access to the system bus for some bus cycles, when the CPU and DMA are targeting the same destination (memory or peripheral). The bus matrix implements round-robin scheduling, thus ensuring at least half of the system bus bandwidth (both to memory and peripheral) for the CPU.

### 8.3.1 DMA transactions

After an event, the peripheral sends a request signal to the DMA Controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA Controller accesses the peripheral, an Acknowledge is sent to the peripheral by the DMA Controller. The peripheral releases its request as soon as it gets the Acknowledge from the DMA Controller. Once the request is deasserted by the peripheral, the DMA Controller release the Acknowledge. If there are more requests, the peripheral can initiate the next transaction.

In summary, each DMA transfer consists of three operations:

- The loading of data from the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base peripheral/memory address programmed in the DMA\_CPARx or DMA\_CMARx register
- The storage of the data loaded to the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start

address used for the first transfer is the base peripheral/memory address programmed in the DMA\_CPARx or DMA\_CMARx register

- The post-decrementing of the DMA\_CNDTRx register, which contains the number of transactions that have still to be performed.

### 8.3.2 Arbiter

The arbiter manages the channel requests based on their priority and launches the peripheral/memory access sequences.

The priorities are managed in two stages:

- Software: each channel priority can be configured in the DMA\_CCRx register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: if 2 requests have the same software priority level, the channel with the lowest number will get priority versus the channel with the highest number. For example, channel 2 gets priority over channel 4.

### 8.3.3 DMA channels

Each channel can handle DMA transfer between a peripheral register located at a fixed address and a memory address. The amount of data to be transferred (up to 65535) is programmable. The register which contains the amount of data items to be transferred is decremented after each transaction.

#### Programmable data sizes

Transfer data sizes of the peripheral and memory are fully programmable through the PSIZE and MSIZE bits in the DMA\_CCRx register.

#### Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented after each transaction depending on the PINC and MINC bits in the DMA\_CCRx register. If incremented mode is enabled, the address of the next transfer will be the address of the previous one incremented by 1, 2 or 4 depending on the chosen data size. The first transfer address is the one programmed in the DMA\_CPARx/DMA\_CMARx registers. During transfer operations, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel is configured in noncircular mode, no DMA request is served after the last transfer (that is once the number of data items to be transferred has reached zero). In order to reload a new number of data items to be transferred into the DMA\_CNDTRx register, the DMA channel must be disabled.

*Note: If a DMA channel is disabled, the DMA registers are not reset. The DMA channel registers (DMA\_CCRx, DMA\_CPARx and DMA\_CMARx) retain the initial values programmed during the channel configuration phase.*

In circular mode, after the last transfer, the DMA\_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the DMA\_CPARx/DMA\_CMARx registers.

### Channel configuration procedure

The following sequence should be followed to configure a DMA channelx (where x is the channel number).

1. Set the peripheral register address in the DMA\_CPARx register. The data will be moved from/ to this address to/ from the memory after the peripheral event.
2. Set the memory address in the DMA\_CMARx register. The data will be written to or read from this memory after the peripheral event.
3. Configure the total number of data to be transferred in the DMA\_CNDTRx register. After each peripheral event, this value will be decremented.
4. Configure the channel priority using the PL[1:0] bits in the DMA\_CCRx register
5. Configure data transfer direction, circular mode, peripheral & memory incremented mode, peripheral & memory data size, and interrupt after half and/or full transfer in the DMA\_CCRx register
6. Activate the channel by setting the ENABLE bit in the DMA\_CCRx register.

As soon as the channel is enabled, it can serve any DMA request from the peripheral connected on the channel.

Once half of the bytes are transferred, the half-transfer flag (HTIF) is set and an interrupt is generated if the Half-Transfer Interrupt Enable bit (HTIE) is set. At the end of the transfer, the Transfer Complete Flag (TCIF) is set and an interrupt is generated if the Transfer Complete Interrupt Enable bit (TCIE) is set.

### Circular mode

Circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA\_CCRx register. When circular mode is activated, the number of data to be transferred is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

### Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This mode is called Memory to Memory mode.

If the MEM2MEM bit in the DMA\_CCRx register is set, then the channel initiates transfers as soon as it is enabled by software by setting the Enable bit (EN) in the DMA\_CCRx register. The transfer stops once the DMA\_CNDTRx register reaches zero. Memory to Memory mode may not be used at the same time as Circular mode.

## 8.3.4 Programmable data width, data alignment and endians

When PSIZE and MSIZE are not equal, the DMA performs some data alignments as described in [Table 30: Programmable data width & endian behavior \(when bits PINC = MINC = 1\)](#).

**Table 30. Programmable data width & endian behavior (when bits PINC = MINC = 1)**

Source port width	Destination port width	Number of data items to transfer (NDT)	Source content: address / data	Transfer operations	Destination content: address / data
8	8	4	@0x0 / B0 @0x1 / B1 @0x2 / B2 @0x3 / B3	1: READ B0[7:0] @0x0 then WRITE B0[7:0] @0x0 2: READ B1[7:0] @0x1 then WRITE B1[7:0] @0x1 3: READ B2[7:0] @0x2 then WRITE B2[7:0] @0x2 4: READ B3[7:0] @0x3 then WRITE B3[7:0] @0x3	@0x0 / B0 @0x1 / B1 @0x2 / B2 @0x3 / B3

**Addressing an AHB peripheral that does not support byte or halfword write operations**

When the DMA initiates an AHB byte or halfword write operation, the data are duplicated on the unused lanes of the HWDATA[31:0] bus. So when the used AHB slave peripheral does not support byte or halfword write operations (when HSIZE is not used by the peripheral) and does not generate any error, the DMA writes the 32 HWDATA bits as shown in the two examples below:

- To write the halfword “0xABCD”, the DMA sets the HWDATA bus to “0xABCDABCD” with HSIZE = HalfWord
- To write the byte “0xAB”, the DMA sets the HWDATA bus to “0xABABABAB” with HSIZE = Byte

Assuming that the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take the HSIZE data into account, it will transform any AHB byte or halfword operation into a 32-bit APB operation in the following manner:

- an AHB byte write operation of the data “0xB0” to 0x0 (or to 0x1, 0x2 or 0x3) will be converted to an APB word write operation of the data “0xB0B0B0B0” to 0x0
- an AHB halfword write operation of the data “0xB1B0” to 0x0 (or to 0x2) will be converted to an APB word write operation of the data “0xB1B0B1B0” to 0x0

For instance, if you want to write the APB backup registers (16-bit registers aligned to a 32-bit address boundary), you must configure the memory source size (MSIZE) to “16-bit” and the peripheral destination size (PSIZE) to “32-bit”.

### 8.3.5 Error management

A DMA transfer error can be generated by reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or a write access, the faulty channel is automatically disabled through a hardware clear of its EN bit in the corresponding Channel configuration register (DMA\_CCRx). The channel's transfer error interrupt flag (TEIF) in the DMA\_IFR register is set and an interrupt is generated if the transfer error interrupt enable bit (TEIE) in the DMA\_CCRx register is set.

### 8.3.6 Interrupts

An interrupt can be produced on a Half-transfer, Transfer complete or Transfer error for each DMA channel. Separate interrupt enable bits are available for flexibility.

**Table 31. DMA interrupt requests**

Interrupt event	Event flag	Enable Control bit
Half-transfer	HTIF	HTIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

### 8.3.7 DMA request mapping

#### DMA controller

The 7 requests from the peripherals (TIMx[2,3,4,6,7], ADC1, SPI[1,2], I2Cx[1,2], USARTx[1,2,3]) and DAC Channelx[1,2] are simply logically ORed before entering the DMA, this means that only one request must be enabled at a time. Refer to [Figure 25: DMA request mapping](#).

The peripheral DMA requests can be independently activated/de-activated by programming the DMA control bit in the registers of the corresponding peripheral.

Figure 25. DMA request mapping

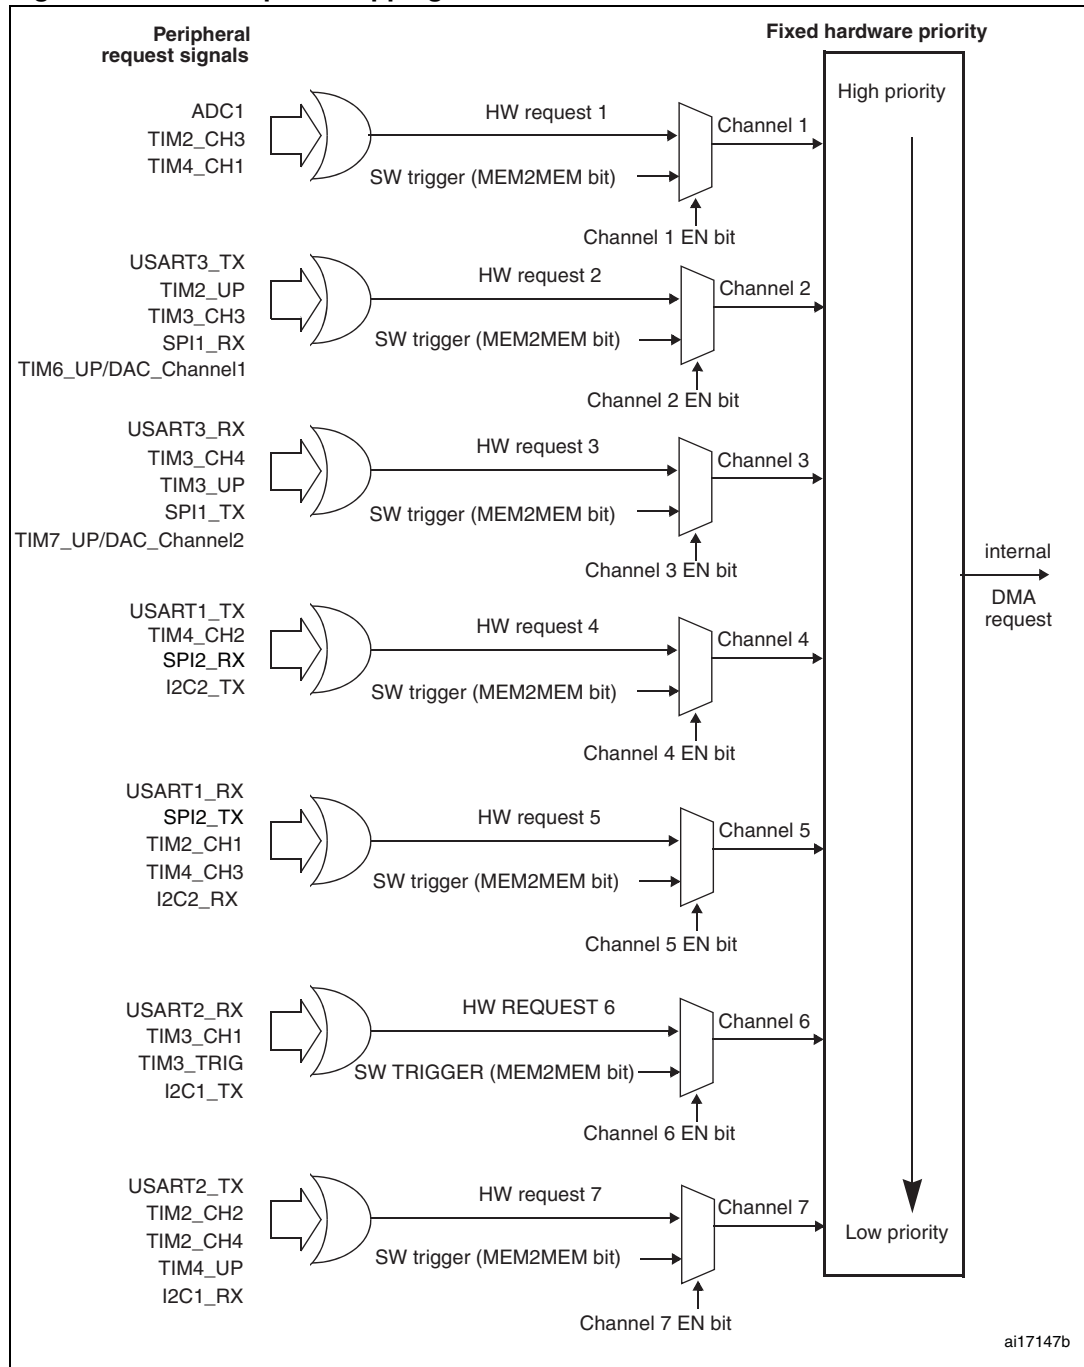

Table 32 lists the DMA requests for each channel.

**Table 32. Summary of DMA requests for each channel**

Peripherals	Channel 1	Channel 2	Channel 3	Channel 4	Channel 5	Channel 6	Channel 7
ADC1	ADC1						
SPI		SPI1_RX	SPI1_TX	SPI2_RX	SPI2_TX		
USART		USART3_TX	USART3_RX	USART1_TX	USART1_RX	USART2_RX	USART2_TX
I <sup>2</sup> C				I2C2_TX	I2C2_RX	I2C1_TX	I2C1_RX
TIM2	TIM2_CH3	TIM2_UP			TIM2_CH1		TIM2_CH2 TIM2_CH4
TIM3		TIM3_CH3	TIM3_CH4 TIM3_UP			TIM3_CH1 TIM3_TRIG	
TIM4	TIM4_CH1			TIM4_CH2	TIM4_CH3		TIM4_UP
TIM6/DAC_Channel1		TIM6_UP/DAC_Channel1					
TIM7/DAC_Channel2			TIM7_UP/DAC_Channel2				

## 8.4 DMA registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by bytes (8-bit), half-words (16-bit) or words (32-bit).

### 8.4.1 DMA interrupt status register (DMA\_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved				TEIF7	HTIF7	TCIF7	GIF7	TEIF6	HTIF6	TCIF6	GIF6	TEIF5	HTIF5	TCIF5	GIF5
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TEIF4	HTIF4	TCIF4	GIF4	TEIF3	HTIF3	TCIF3	GIF3	TEIF2	HTIF2	TCIF2	GIF2	TEIF1	HTIF1	TCIF1	GIF1
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, always read as 0.

Bits 27, 23, 19, 15, 11, 7, 3 **TEIFx**: Channel x transfer error flag (x = 1 ..7)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_IFCR register.  
 0: No transfer error (TE) on channel x  
 1: A transfer error (TE) occurred on channel x

Bits 26, 22, 18, 14, 10, 6, 2 **HTIFx**: Channel x half transfer flag (x = 1 ..7)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_IFCR register.  
 0: No half transfer (HT) event on channel x  
 1: A half transfer (HT) event occurred on channel x

Bits 25, 21, 17, 13, 9, 5, 1 **TCIFx**: Channel x transfer complete flag (x = 1 ..7)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_IFCR register.  
 0: No transfer complete (TC) event on channel x  
 1: A transfer complete (TC) event occurred on channel x

Bits 24, 20, 16, 12, 8, 4, 0 **GIFx**: Channel x global interrupt flag (x = 1 ..7)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_IFCR register.  
 0: No TE, HT or TC event on channel x  
 1: A TE, HT or TC event occurred on channel x

### 8.4.2 DMA interrupt flag clear register (DMA\_IFCR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved				CTEIF7	CHTIF7	CTCIF7	CGIF7	CTEIF6	CHTIF6	CTCIF6	CGIF6	CTEIF5	CHTIF5	CTCIF5	CGIF5
				w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTEIF4	CHTIF4	CTCIF4	CGIF4	CTEIF3	CHTIF3	CTCIF3	CGIF3	CTEIF2	CHTIF2	CTCIF2	CGIF2	CTEIF1	CHTIF1	CTCIF1	CGIF1
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:28 Reserved, always read as 0.

Bits 27, 23, 19, 15, **CTEIFx**: Channel x transfer error clear (x = 1 ..7)

11, 7, 3 This bit is set and cleared by software.

0: No effect

1: Clears the corresponding TEIF flag in the DMA\_ISR register

Bits 26, 22, 18, 14, **CHTIFx**: Channel x half transfer clear (x = 1 ..7)

10, 6, 2 This bit is set and cleared by software.

0: No effect

1: Clears the corresponding HTIF flag in the DMA\_ISR register

Bits 25, 21, 17, 13, **CTCIFx**: Channel x transfer complete clear (x = 1 ..7)

9, 5, 1 This bit is set and cleared by software.

0: No effect

1: Clears the corresponding TCIF flag in the DMA\_ISR register

Bits 24, 20, 16, 12, **CGIFx**: Channel x global interrupt clear (x = 1 ..7)

8, 4, 0 This bit is set and cleared by software.

0: No effect

1: Clears the GIF, TEIF, HTIF and TCIF flags in the DMA\_ISR register

### 8.4.3 DMA channel x configuration register (DMA\_CCRx) (x = 1..7, where x = channel number)

Address offset: 0x08 + 0d20 × (channel number – 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, always read as 0.

Bit 14 **MEM2MEM**: Memory to memory mode  
 This bit is set and cleared by software.  
 0: Memory to memory mode disabled  
 1: Memory to memory mode enabled

Bits 13:12 **PL[1:0]**: Channel priority level  
 These bits are set and cleared by software.  
 00: Low  
 01: Medium  
 10: High  
 11: Very high

Bits 11:10 **MSIZE[1:0]**: Memory size  
 These bits are set and cleared by software.  
 00: 8-bits  
 01: 16-bits  
 10: 32-bits  
 11: Reserved

Bits 9:8 **PSIZE[1:0]**: Peripheral size  
 These bits are set and cleared by software.  
 00: 8-bits  
 01: 16-bits  
 10: 32-bits  
 11: Reserved

Bit 7 **MINC**: Memory increment mode  
 This bit is set and cleared by software.  
 0: Memory increment mode disabled  
 1: Memory increment mode enabled

Bit 6 **PINC**: Peripheral increment mode  
 This bit is set and cleared by software.  
 0: Peripheral increment mode disabled  
 1: Peripheral increment mode enabled

Bit 5 **CIRC**: Circular mode  
 This bit is set and cleared by software.  
 0: Circular mode disabled  
 1: Circular mode enabled

- Bit 4 **DIR**: Data transfer direction  
 This bit is set and cleared by software.  
 0: Read from peripheral  
 1: Read from memory
- Bit 3 **TEIE**: Transfer error interrupt enable  
 This bit is set and cleared by software.  
 0: TE interrupt disabled  
 1: TE interrupt enabled
- Bit 2 **HTIE**: Half transfer interrupt enable  
 This bit is set and cleared by software.  
 0: HT interrupt disabled  
 1: HT interrupt enabled
- Bit 1 **TCIE**: Transfer complete interrupt enable  
 This bit is set and cleared by software.  
 0: TC interrupt disabled  
 1: TC interrupt enabled
- Bit 0 **EN**: Channel enable  
 This bit is set and cleared by software.  
 0: Channel disabled  
 1: Channel enabled

### 8.4.4 DMA channel x number of data register (DMA\_CNDTRx) (x = 1..7), where x = channel number)

Address offset: 0x0C + 0d20 × (channel number – 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NDT															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, always read as 0.

Bits 15:0 **NDT[15:0]**: Number of data to transfer

Number of data to be transferred (0 up to 65535). This register can only be written when the channel is disabled. Once the channel is enabled, this register is read-only, indicating the remaining bytes to be transmitted. This register decrements after each DMA transfer.

Once the transfer is completed, this register can either stay at zero or be reloaded automatically by the value previously programmed if the channel is configured in auto-reload mode.

If this register is zero, no transaction can be served whether the channel is enabled or not.

**8.4.5 DMA channel x peripheral address register (DMA\_CPARx) (x = 1..7), where x = channel number)**

Address offset:  $0x10 + 0d20 \times (\text{channel number} - 1)$

Reset value: 0x0000 0000

This register must *not* be written when the channel is enabled.

Bits 31:0 **PA[31:0]**: Peripheral address

Base address of the peripheral data register from/to which the data will be read/written.

When PSIZE is 01 (16-bit), the PA[0] bit is ignored. Access is automatically aligned to a half-word address.

When PSIZE is 10 (32-bit), PA[1:0] are ignored. Access is automatically aligned to a word address.

**8.4.6 DMA channel x memory address register (DMA\_CMARx) (x = 1..7), where x = channel number)**

Address offset:  $0x14 + 0d20 \times (\text{channel number} - 1)$

Reset value: 0x0000 0000

This register must *not* be written when the channel is enabled.

Bits 31:0 **MA[31:0]**: Memory address

Base address of the memory area from/to which the data will be read/written.

When MSIZE is 01 (16-bit), the MA[0] bit is ignored. Access is automatically aligned to a half-word address.

When MSIZE is 10 (32-bit), MA[1:0] are ignored. Access is automatically aligned to a word address.

### 8.4.7 DMA register map

The following table gives the DMA register map and the reset values.

**Table 33. DMA register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 9 Analog-to-digital converter (ADC)

### 9.1 ADC introduction

The 12-bit ADC is a successive approximation analog-to-digital converter. It has up to 26 multiplexed channels allowing it measure signals from 24 external and two internal sources. The A/D conversion of the channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored into a left- or right-aligned 16-bit data register.

The analog watchdog feature allows the application to detect if the input voltage goes beyond the user-defined, higher or lower thresholds.

Conversions are always performed at maximum speed to have the highest possible conversion rate for a given system clock frequency. The automatic power control dramatically reduces the consumption by powering-on the ADC only during conversions.

### 9.2 ADC main features

- 12-bit, 10-bit, 8-bit or 6-bit configurable resolution
- Interrupt generation at the end of regular conversions, end of injected conversions, and in case of analog watchdog or overrun events (for regular conversions)
- Single and continuous conversion modes
- Scan mode for automatic conversions in a fully programmable order
- Programmable data alignment with in-built data coherency
- Programmable and individual sampling time for each ADC channel
- External trigger option with configurable edge detection for both regular and injected conversions
- Discontinuous mode
- ADC conversion time: 1  $\mu$ s at full speed (ADC clocked at 16 MHz) down to 4  $\mu$ s at low speed (ADC clocked at 4 MHz), independent of the APB clock
- Automatic power-up/power-down to reduce the power consumption
- ADC supply requirements:
  - 2.4 V to 3.6 V at full speed or with reference zooming ( $V_{REF+} < V_{DDA}$ )
  - down to 1.8 V at slower speeds
- ADC input range:  $V_{REF-} \leq V_{IN} \leq V_{REF+}$
- Automatic programmable hardware delay insertion between conversions
- DMA request generation during regular channel conversion

*Figure 26* shows the block diagram of the ADC.

*Note:*  $V_{REF-}$ , if available (depending on package), must be tied to  $V_{SSA}$ .

### 9.3 ADC functional description

*Figure 26* shows the ADC block diagram, *Table 34* gives the pin description.

Figure 26. ADC block diagram

Note: Due to internal connections (ADC multiplexer switches), ADC channels 4, 5, 22, 23, 24 and 25 are considered as fast channels (up to 1 Msample/s) and the other channels are slower (they do not exceed 800 ksamples/s). For more details, refer to [Figure 20: Routing interface \(RI\) block diagram on page 127](#).

Table 34. ADC pins

Name	Signal type	Remarks
$V_{REF+}$	Input, analog reference positive	<p>The higher/positive reference voltage for the ADC is:</p> <p><math>2.4V \leq V_{REF+} = V_{DDA}</math> for full speed (ADCCLK = 16 MHz, 1 Msps)</p> <p><math>1.8V \leq V_{REF+} = V_{DDA}</math> for medium speed (ADCCLK = 8 MHz, 500 Ksps)</p> <p><math>2.4V \leq V_{REF+} \neq V_{DDA}</math> for medium speed (ADCCLK = 8 MHz, 500 Ksps)</p> <p><math>1.8V \leq V_{REF+} &lt; V_{DDA}</math> for low speed (ADCCLK = 4 MHz, 250 Ksps)</p> <p>When product voltage range 3 is selected (<math>V_{CORE} = 1.2 V</math>), the ADC is low speed (ADCCLK = 4 MHz, 250 Ksps)</p>

### 9.3.1 ADC power on-off control

The ADC is powered on by setting the ADON bit in the ADC\_CR2 register. When the ADON bit is set for the first time, it wakes up the ADC from the Power-down mode.

Conversion starts when either the SWSTART or the JSWSTART bit is set, or in response to an external trigger. These software or hardware triggers must be enabled only when the ADC is ready to convert (ADONS=1).

Resetting the ADON bit stops the conversions and put the ADC in power down mode. In this mode the ADC consumes almost no power. ADONS is cleared after ADON has been synchronized to the ADCCLK clock domain.

*Note:* Due to the latency introduced by the synchronization between the two clock domains, ADON must be set only when ADONS=0 and it must be cleared only when the ADC is ready to convert (ADONS=1).

#### Power down configurations (PDI and PDD)

In order to reduce the consumption when the ADC is ready to convert (ADONS=1), the ADC can be automatically powered off when it is not converting, until the next conversion starts depending on the PDI and PDD bits in the ADC\_CR1 register. Refer to [Section 9.10: Power saving on page 188](#) for more details.

Using the PDI bit, the user can determine whether the ADC is powered up or down when it is not converting (waiting for a hardware or software trigger event).

Using the PDD bit, the user can determine whether the ADC is powered up or down between 2 conversions (or sequences of conversions) when a delay is inserted (DELS bits).

When PDI=1, ADONS is the image of ADON (same value) as viewed from the ADCCLK clock.

Conversion starts after the ADC power-up time ( $t_{STAB}$ ) when either the SWSTART or the JSWSTART bit is set, or in response to an external trigger. These software or hardware triggers must be enabled only when the ADC is ready to convert (ADONS=1).

Resetting the ADON bit stops the conversions and places the ADC in a mode where it is no longer supplied.

*Note:* Due to the latency introduced by the synchronization between the two clock domains, ADON must be set only when ADONS=0 and it must be cleared only when ADONS=1.

### 9.3.2 ADC clock

To avoid unnecessary consumption while not converting, the ADC digital interface has been designed to operate in a completely independent manner, at its maximum speed using an internal 16 MHz clock source (HSI), whatever the CPU operating frequency (which can range from a few sub-kHz up to 32 MHz).

*Note:* When entering Stop mode, the ADC analog and digital interfaces remain inactive as the HSI and PCLK2 are disabled. Since the HSI is still deactivated after resuming from Stop mode, the user must enable the HSI as the ADC analog interface clock source and continue using ADC conversions.

The ADCCLK clock is provided by the clock controller. It is generated from the HSI oscillator after a clock divider:

- by 1 for full speed ( $f_{ADCCLK} = 16 \text{ MHz}$ )
- by 2 for medium speed and by 4 for low speed ( $f_{ADCCLK} = 4 \text{ MHz}$ )

Depending on the APB clock (PCLK) frequency, the ADCCLK clock frequency can be higher or lower than PCLK. In particular, when the APB becomes too low, it can become difficult to get the results of conversions at full speed without losing any data (because the data flow is higher than what the CPU or the DMA can handle). This problem can be solved by inserting a delay between 2 conversions or between 2 sequences of conversions in order to give the system enough time to read and save the converted data before the next data arrive. Refer to [Section 9.9: Hardware freeze and delay insertion modes for slow conversions on page 185](#) for more details.

### 9.3.3 Channel selection

There are 26 multiplexed channels. It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: Ch3, Ch8, Ch2, Ch2, Ch0, Ch2, Ch2, Ch15.

- A **regular group** is composed of up to 27 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC\_SQRx registers. The total number of conversions, which can be up to 27 in the regular group must be written in the L[4:0] bits in the ADC\_SQR1 register.

- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC\_JSQR register. The total number of conversions, which can be up to 4 in the injected group must be written in the L[1:0] bits in the ADC\_JSQR register.

*Note:* If the ADC\_SQRx register is modified during a regular conversion or the ADC\_JSQR register is modified during an injected conversion, the current conversion is reset and the ADC waits for a new start pulse. If the conversion that is reset is an injected conversion that had interrupted a regular conversion, then the regular conversion is resumed.

### Temperature sensor, V<sub>REFINT</sub> internal channels

The temperature sensor is connected to channel ADCx\_IN16 and the internal reference voltage V<sub>REFINT</sub> is connected to ADCx\_IN17. These two internal channels can be selected and converted as injected or regular channels.

## 9.3.4 Single conversion mode

In Single conversion mode the ADC does one conversion. This mode is started with the CONT bit in the ADC\_CR2 at 0 by either:

- setting the SWSTART bit in the ADC\_CR2 register (for a regular channel only)
- setting the JSWSTART bit (for an injected channel)
- external trigger (for a regular or injected channel)

Once the conversion of the selected channel is complete:

- If a regular channel was converted (converted channel is selected by the SQ1[4:0] bits in the SQR5 register):
  - The converted data are stored into the 16-bit ADC\_DR register
  - The EOC (end of conversion) flag is set
  - An interrupt is generated if the EOCIE bit is set
- If an injected channel was converted (converted channel is selected by the JSQ1[4:0] bits in the JSQR register):
  - The converted data are stored into the 16-bit ADC\_JDR1 register
  - The JEOC (end of conversion injected) flag is set
  - An interrupt is generated if the JEOCIE bit is set

Then the ADC stops.

## 9.3.5 Continuous conversion mode

In continuous conversion mode, the ADC starts a new conversion as soon as it finishes one. This mode is started with the CONT bit at 1 either by external trigger or by setting the SWSTART bit in the ADC\_CR2 register (for regular channels only).

After each conversion:

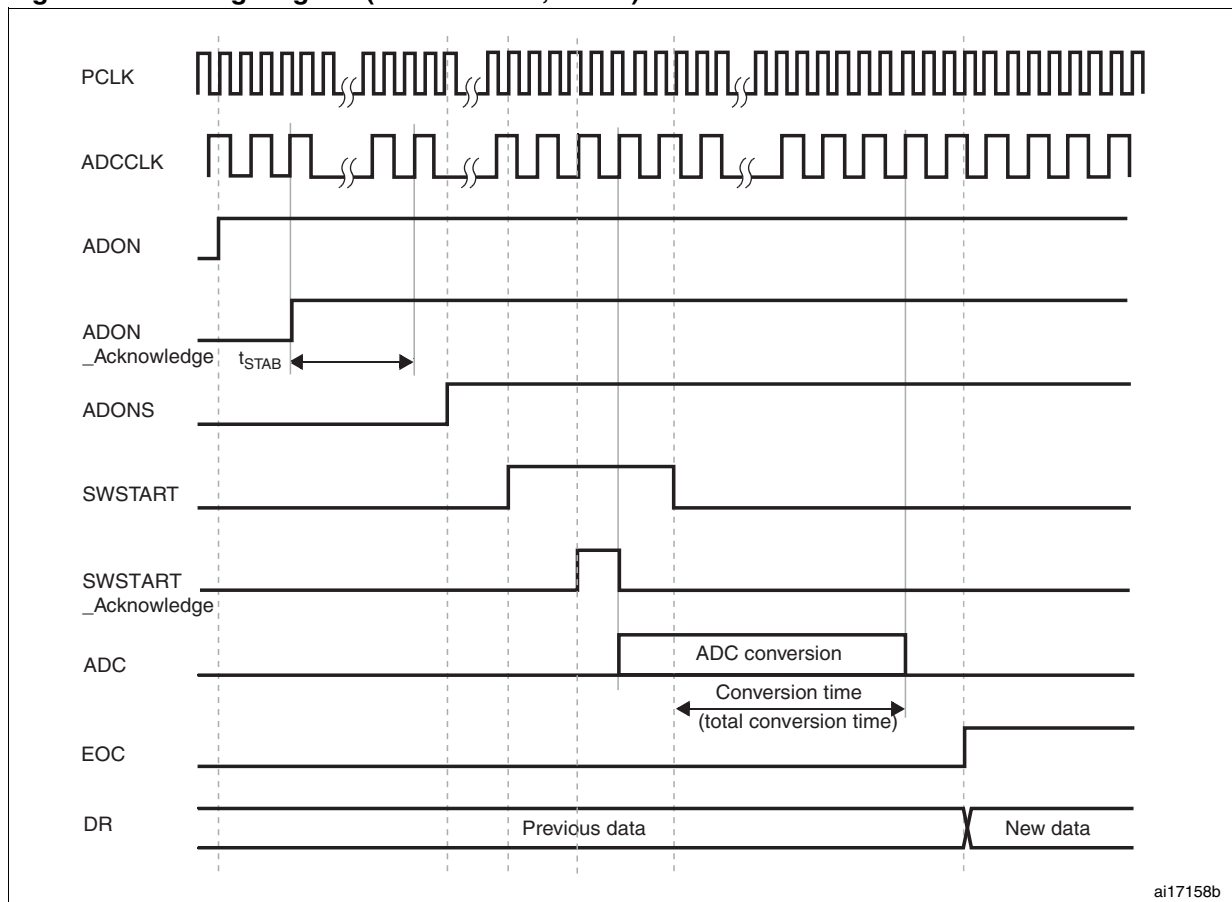

- If a regular channel was converted (converted channel is selected by the SQ1[4:0] bits in the SQR5 register):
  - The last converted data are stored into the 16-bit ADC\_DR register
  - The EOC (end of conversion) flag is set
  - An interrupt is generated if the EOCIE bit is set

*Note:* Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to [Auto-injected conversion](#) section).

### 9.3.6 Timing diagram

As shown in [Figure 27](#), the ADC needs a stabilization time ( $t_{STAB}$ ) before it can actually convert. The ADONS bit is set when a conversion can be triggered. A conversion is launched when the SWSTART bit is set (or when an external trigger is detected). After the conversion time (programmable sampling time + 12 ADCCLK clock cycles for 12-bit data), the EOC flag is set and the ADC data register contains the result of the conversion. Note that some delays are needed to resynchronize the different signals from one clock domain to the other.

**Figure 27. Timing diagram (normal mode, PDI=0)**

### 9.3.7 Analog watchdog

The AWD analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold. These thresholds are programmed in the 12 least significant bits of the ADC\_HTR and ADC\_LTR 16-bit registers. An interrupt can be enabled by using the AWDIE bit in the ADC\_CR1 register.

The threshold value is independent of the alignment selected by the ALIGN bit in the ADC\_CR2 register. The analog voltage is compared to the lower and higher thresholds before alignment.

Table 35 shows how the ADC\_CR1 register should be configured to enable the analog watchdog on one or more channels.

Figure 28. Analog watchdog’s guarded area

Table 35. Analog watchdog channel selection

Channels guarded by the analog watchdog	ADC_CR1 register control bits (x = don't care)		
	AWDSGL bit	AWDEN bit	JAWDEN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single <sup>(1)</sup> injected channel	1	0	1
Single <sup>(1)</sup> regular channel	1	1	0
Single <sup>(1)</sup> regular or injected channel	1	1	1

1. Selected by the AWDCH[4:0] bits

### 9.3.8 Scan mode

This mode is used to scan a group of analog channels.

The Scan mode is selected by setting the SCAN bit in the ADC\_CR1 register. Once this bit has been set, the ADC scans all the channels selected in the ADC\_SQRx registers (for regular channels) or in the ADC\_JSQR register (for injected channels). A single conversion is performed for each channel of the group. After each end of conversion, the next channel in the group is converted automatically. If the CONT bit in the ADC\_CR2 register is set, regular channel conversion does not stop at the last selected channel in the group but continues again from the first selected channel.

If the DMA bit is set, the direct memory access (DMA) controller is used to transfer the data converted from the regular group of channels (stored in the ADC\_DR register) to memory after each regular channel conversion.

The EOC bit is set in the ADC\_SR register if:

- At the end of each regular group sequence the EOCS bit is cleared to 0
- At the end of each regular channel conversion the EOCS bit is set to 1

The data converted from an injected channel is always stored into the ADC\_JDRx registers.

### 9.3.9 Injected channel management

#### Triggered injected conversion

To use triggered injection, the JAUTO bit must be cleared in the ADC\_CR1 register.

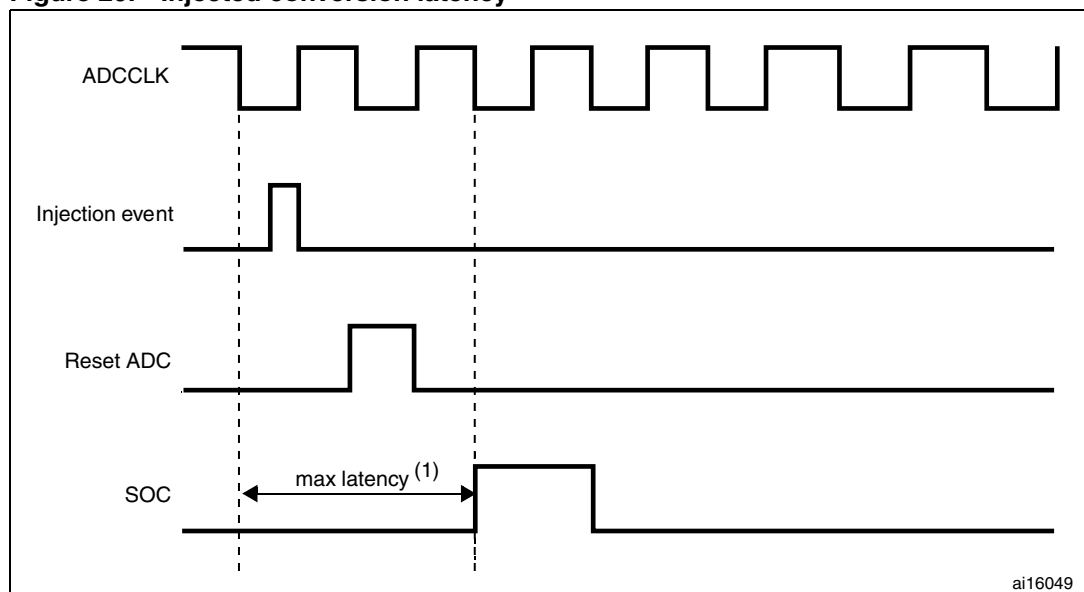

1. Start the conversion of a group of injected channels either by external trigger or by setting the JSWSTART bit in the ADC\_CR2 register.
2. If an external injected trigger occurs or if the JSWSTART bit is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches to Scan-once mode.
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence.

Figure 29 shows the corresponding timing diagram.

*Note:* When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 3 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

**Figure 29. Injected conversion latency**

1. The maximum latency value can be found in the electrical characteristics of the STM32L15xxx datasheet.

#### Auto-injected conversion

If the JAUTO bit is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 31 conversions programmed in the ADC\_SQRx and ADC\_JSQR registers.

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

*Note:* It is not possible to use both the auto-injected and discontinuous modes simultaneously.

### 9.3.10 Discontinuous mode

#### Regular group

This mode is enabled by setting the DISCEN bit in the ADC\_CR1 register. It can be used to convert a short sequence of  $n$  conversions ( $n \leq 8$ ) that is part of the sequence of conversions selected in the ADC\_SQRx registers. The value of  $n$  is specified by writing to the DISCNUM[2:0] bits in the ADC\_CR1 register.

When an external trigger occurs, it starts the next  $n$  conversions selected in the ADC\_SQRx registers until all the conversions in the sequence are done. The total sequence length is defined by the L[4:0] bits in the ADC\_SQR1 register.

Example:

$n = 3$ , regular channels to be converted = 0, 1, 2, 3, 6, 7, 9, 10  
 1st trigger: sequence converted 0, 1, 2  
 2nd trigger: sequence converted 3, 6, 7  
 3rd trigger: sequence converted 9, 10 and an EOC event generated  
 4th trigger: sequence converted 0, 1, 2

*Note:* When a regular group is converted in discontinuous mode, no rollover occurs.  
 When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 0, 1 and 2 in the 1st subgroup.

#### Injected group

This mode is enabled by setting the JDISCEN bit in the ADC\_CR1 register. It can be used to convert a short sequence of  $n$  conversions ( $n \leq 3$ ) part of the sequence of conversions selected in the ADC\_JSQR registers. The value of  $n$  is specified by writing to the DISCNUM[2:0] bits in the ADC\_CR1 register.

When an external trigger occurs, it starts the next channel conversions selected in the ADC\_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC\_JSQR register.

Example:

$n = 1$ , injected channels to be converted = 1, 2, 3  
 1st trigger: channel 1 converted  
 2nd trigger: channel 2 converted  
 3rd trigger: channel 3 converted and EOC and JEEOC events generated  
 4th trigger: channel 1

*Note:* 1 When all injected channels are converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.  
 2 It is not possible to use both the auto-injected and discontinuous modes simultaneously.  
 3 Discontinuous mode must not be set for regular and injected groups at the same time.

## 9.4 Data alignment

The ALIGN bit in the ADC\_CR2 register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in [Figure 30](#) and [Figure 31](#).

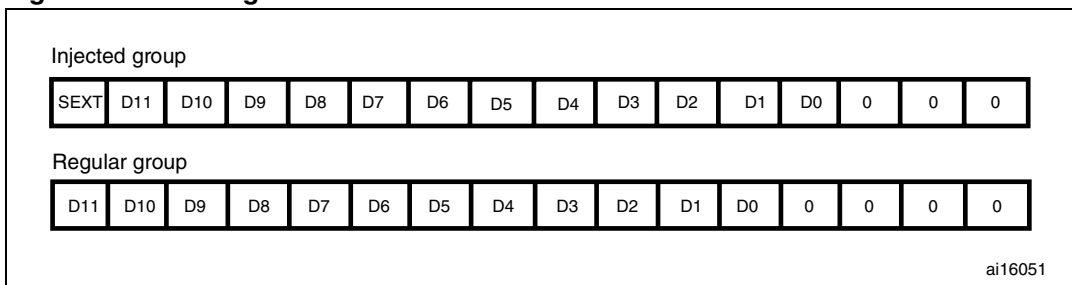

The converted data value from the injected group of channels is decreased by the user-defined offset written in the ADC\_JOFRx registers so the result can be a negative value. The SEXT bit represents the extended sign value.

For channels in a regular group, no offset is subtracted so only twelve bits are significant.

**Figure 30. Right alignment of 12-bit data**

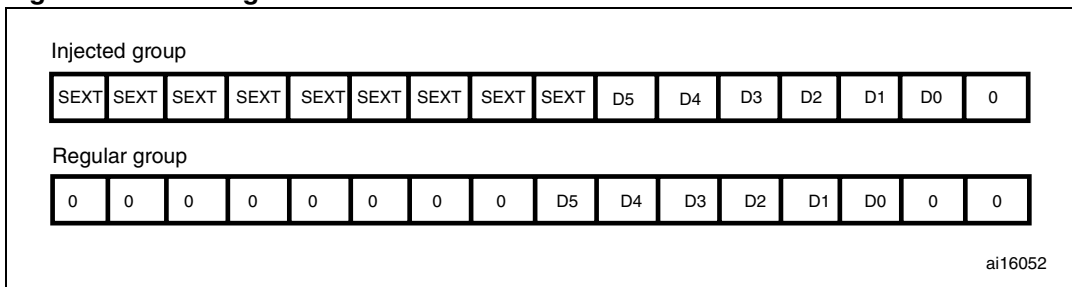

**Figure 31. Left alignment of 12-bit data**

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in [Figure 32](#).

**Figure 32. Left alignment of 6-bit data**

## 9.5 Channel-wise programmable sampling time

The ADC samples the input voltage for a number of ADCCLK cycles that can be modified using the SMP[2:0] bits in the ADC\_SMPRx registers (x =1 to 3). Each channel can be sampled with a different sampling time.

The total conversion time is calculated as follows:

$$T_{conv} = \text{Sampling time} + \text{channel conversion time}$$

Example:

With ADCCLK = 16 MHz and sampling time = 4 cycles:

$T_{conv} = 4 + 12 = 16$  cycles = 1  $\mu$ s (for 12-bit conversion)

$T_{conv} = 4 + 7 = 11$  cycles = 685 ns (for 6-bit conversion)

## 9.6 Conversion on external trigger

Conversion can be triggered by an external event (e.g. timer capture, EXTI line). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from “0b00”, then external events are able to trigger a conversion with the selected edge. [Table 36](#) provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger edge.

**Table 36. Configuring the trigger edge detection**

Source	EXTEN[1:0] / JEXTEN[1:0]
Trigger detection disabled	00
Detection on the rising edge	01
Detection on the falling edge	10
Detection on both the rising and falling edges	11

*Note:* The edge detection of the external trigger can be changed on the fly.

The EXTSEL[3:0] and JEXTSEL[3:0] control bits are used to select which out of 16 possible events can trigger conversion for the regular and injected groups.

[Table 37](#) gives the possible external trigger for regular conversion.

**Table 37. External trigger for regular channels**

Source	Type	EXTSEL[3:0]
TIM9_CC2 event	Internal signal from on-chip timers	0000
TIM9_TRGO event		0001
TIM2_CC3 event		0010

Reserved		NA	1011
Reserved			1100
Reserved	1101		
Reserved	1110		
EXTI line15	External pin	1111	

A regular group conversion can be interrupted by an injected trigger.

- Note: 1 The trigger selection can be changed on the fly. When this is done, however, trigger detection is disabled for a period of 2 PCLK cycles. This is to avoid spurious detections during the transition.
- 2 The interval between trigger events must be longer than:
- the sequence for regular conversions
  - the sequence + 1 ADCCLK cycle for injected conversions
- For instance, if the sequence length is 32 ADC clock cycles (that is two conversions with a 4 clock-period sampling time), the minimum interval between regular triggers must be greater

than 32 ADC clock cycles and the interval between injected triggers must be greater than 33 ADC clock cycles.

## 9.7 Aborting a conversion

### 9.7.1 Injected channels

An injected conversion or a sequence of conversions can be stopped by writing to the JSQR register (the JL[1:0] bitfield has to be written with its current value). Then any ongoing injected conversion aborts and any pending trigger is reset. A new injected conversion can start when a new hardware or software trigger occurs.

After aborting an injected conversion, the system requires a few clock cycles before a new injected conversion can start (3 to 5 ADC clock cycles + 2 to 5 APB clock cycles). To meet this requirement, JSWSTART should not be set before JCNR=0.

### 9.7.2 Regular channels

A regular conversion or a sequence of conversions can be stopped by writing to any of the SQR1 to SQR5 registers (if SQR1 is written, the L[4:0] bitfield has to be written with its current value). The ADC then behaves in the same way as in the case of injected conversions (see [Section 9.7.2: Regular channels](#)).

If several of the SQRi registers have to be written in order to configure a new sequence, no conversion should be launched between the different write accesses. In this case, the following sequence must be applied:

1. Disable the external triggers by writing the EXTEN bits to 00 (when external triggers are used)
2. Change the sequence configuration (by writing to the SQRi registers)
3. Wait for RCNR=0 in the ADC\_SR register
4. Enable the external trigger or set the SWSTART bit

## 9.8 Conversion resolution

It is possible to perform faster conversion by reducing the ADC resolution. The RES[1:0] bits are used to select the number of bits available in the data register. The minimal conversion time for each resolution, when the sampling time is 4 cycles, is then as follows:

- for 12-bit resolution :  $12 + 4 = 16$  cycles
- for 10-bit resolution :  $11 + 4 = 15$  cycles
- for 8-bit resolution :  $9 + 4 = 13$  cycles
- for 6-bit resolution :  $7 + 4 = 11$  cycles

## 9.9 Hardware freeze and delay insertion modes for slow conversions

When the APB clock is not fast enough to manage the data rate, a delay can be introduced between conversions to reduce this data rate. The delay is inserted after each regular

conversion and after each sequence of injected conversions as, during conversion, a trigger event (for the same group of conversions) occurring during this delay is ignored.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the delay of a regular conversion, the injected conversion starts immediately.
- If a regular conversion is to be resumed after being interrupted by an injected sequence, it starts as soon as the delay of the previous regular conversion is finished.

The behavior is slightly different in auto-injected mode where a new regular conversion can start only when the delay of the previous injected conversion has ended. This is to ensure that the software can read all the data of a given sequence before starting a new sequence. In this mode, a regular trigger is ignored if it occurs during the delay that follows a regular conversion. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence or the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

The length of the delay is configured using the DELS[2:0] bits in the ADC\_CR2 register. Two cases should be considered:

- **ADC freeze mode:**  
When DELS[2:0]=001, a new conversion can start only if all the previous data of the same group have been treated:
  - for a regular conversion: once the ADC\_DR register has been read or if the EOC bit has been cleared
  - for an injected conversion: when the JEOC bit has been cleared
- **ADC delay insertion mode:**  
When DELS[2:0]>001, a new conversion can start only after a given number of APB clock cycles after the end of the previous conversion in the same group.

**Figure 33. ADC freeze mode**

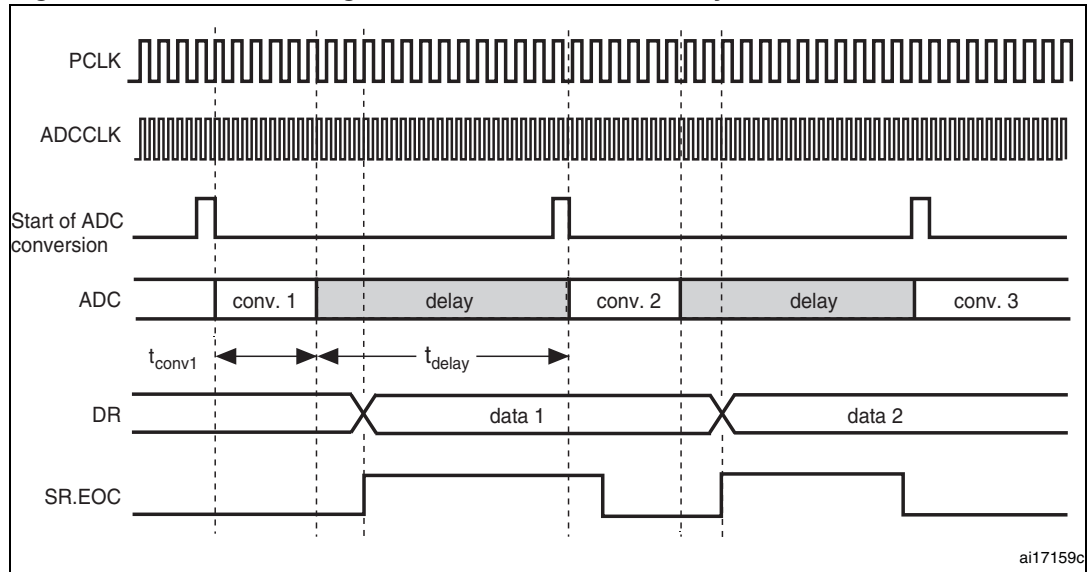

### 9.9.1 Inserting a delay after each regular conversion

When enabled, a delay is inserted at the end of each regular conversion before a new regular conversion can start. It gives time to read the converted data in the ADC\_DR register before a new regular conversion is completed. The length of the delay is configured by the DELS[2:0] bits. [Figure 34](#) shows an example of continuous regular conversions where a 10 PCLK cycle delay is inserted after each conversion.

Note: When `ADC_CR2_EOCS = 1`, the delay is inserted after each sequence of regular group conversions.

Figure 34. Continuous regular conversions with a delay

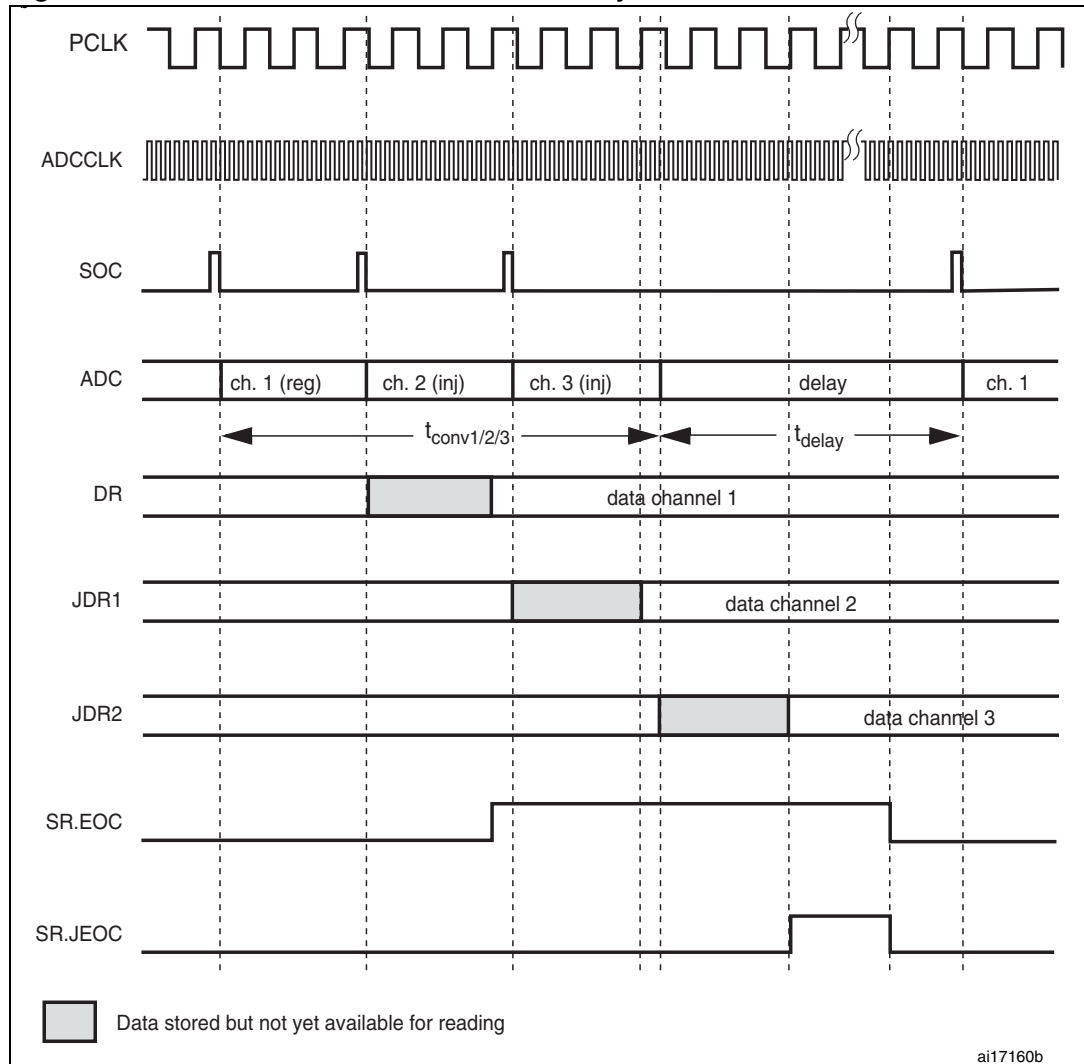

1.  $t_{conv1}$ : including sampling and conversion times (for instance 16 ADC clock cycles with the minimum sampling time)
2.  $t_{delay}$ : delay from the end of a conversion to the start of the next conversion (number of PCLK periods configured with the `DELS[2:0]` bits) + delay to synchronize the end of conversion (0 to 1 PCLK clock cycles) + delay to synchronize the end of delay (2 or 3 ADC clock cycles).

### 9.9.2 Inserting a delay after each sequence of auto-injected conversions

When enabled, a delay is inserted at the end of each sequence of injected conversions. Up to 5 conversion results can be stored into the `ADC_DR` and the `ADC_JDRx` registers. The length of the delay is configured by the `DELS[2:0]` bits. [Figure 35](#) shows an example of continuous conversions (the `CONT` bit is set) where a delay is inserted after each sequence of injected conversions. Here the `JAUTO` bit is set and the sequence ends after the last injected conversion (the sequence is made of 1 regular conversion + 2 injected conversions).

Figure 35. Continuous conversions with a delay between each conversion

1.  $t_{conv1/2/3}$ : including sampling and conversion times for channels 1, 2 and 3.
2.  $t_{delay}$ : delay from the end of the previous sequence to the start of the new sequence (number of PCLK periods configured with the DELS bits) + delay to synchronize the end of conversion (0 to 1 PCLK clock cycles) + delay to synchronize the end of delay (2 or 3 ADC clock cycles).

## 9.10 Power saving

ADC power-on and power-off can be managed by hardware to cut the consumption when the ADC is not converting. The ADC can be powered down:

- during the delay described above (when the PDD bit is set). Then the ADC is powered up again at the end of the delay and/or
- when the ADC is waiting for a trigger event (when the PDI bit is set). In this case the ADC is powered up at the next trigger event.

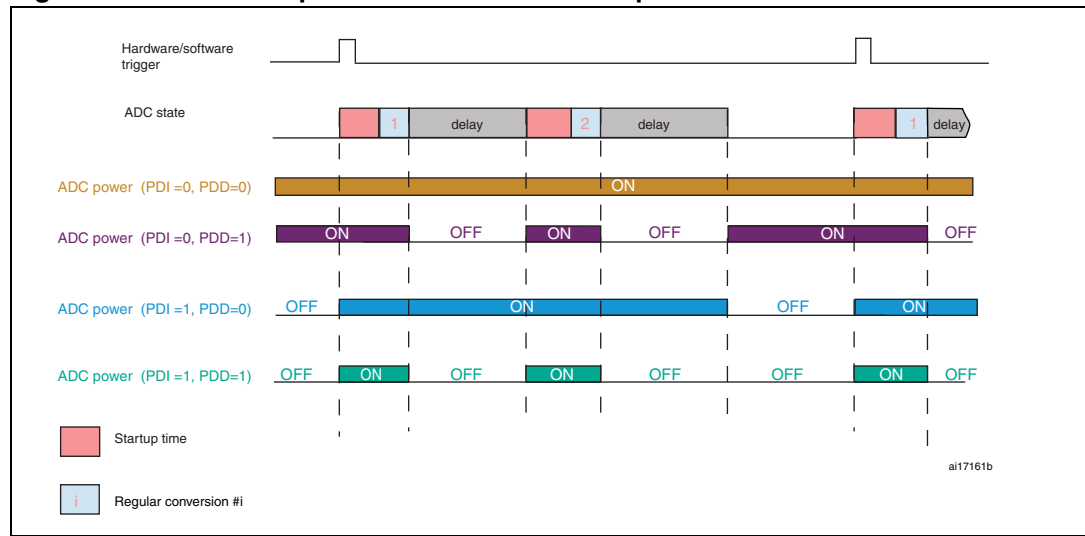

The ADC needs a certain time to start up before a conversion can actually be launched. This startup time must be taken into account before selecting the automatic power control modes or when configuring the delay. For this reason, it is also more efficient (from the

power point of view and when possible) when scanning several channels to launch a sequence of several conversions and stop the consumption after the sequence, than when launching each conversion one by one with a delay after each conversion.

For a given sequence of conversions, the ADCCLK clock must be enabled before launching the first conversion, and be present until the EOC bit (or the JEOC bit in case of injected channels) is set.

Figure 36, Figure 37 and Figure 38 show examples of power management in different configurations. ADON=1 in all these examples.

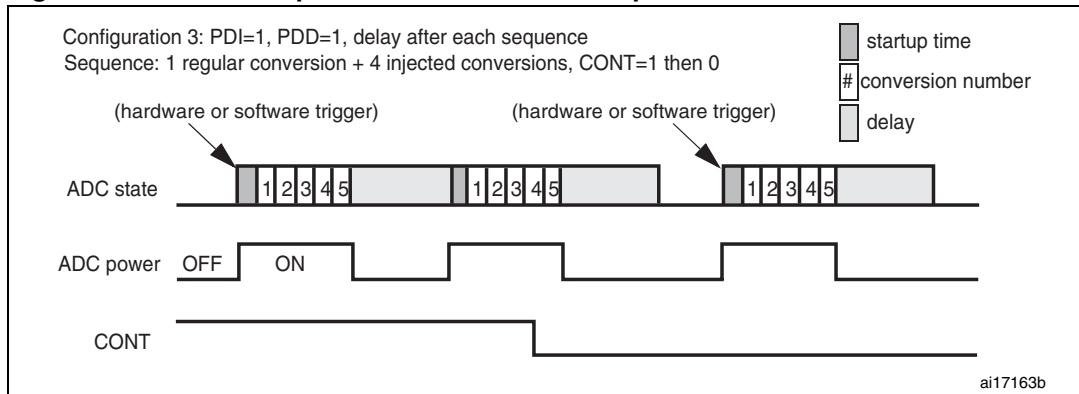

**Figure 36. Automatic power-down control: example 1**

**Figure 37. Automatic power-down control: example 2**

**Figure 38. Automatic power-down control: example 3**

## 9.11 Data management and overrun detection

### 9.11.1 Using the DMA

Since converted regular channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one regular channel. This avoids the loss of the data already stored in the ADC\_DR register.

When the DMA mode is enabled (DMA bit set to 1 in the ADC\_CR2 register), after each conversion of a regular channel, a DMA request is generated. This allows the transfer of the converted data from the ADC\_DR register to the destination location selected by the software.

Despite this, if data are lost (overrun), the OVR bit in the ADC\_SR register is set and an interrupt is generated (if the OVRIE enable bit is set). DMA transfers are then disabled and DMA requests are no longer accepted. In this case, if a DMA request is made, the regular conversion in progress is aborted and further regular triggers are ignored. It is then necessary to clear the OVR flag and the DMAEN bit in the used DMA stream, and to re-initialize both the DMA and the ADC to have the wanted converted channel data transferred to the right memory location. Only then can the conversion be resumed and the data transfer, enabled again. Injected channel conversions are not impacted by overrun errors.

When OVR = 1 in DMA mode, the DMA requests are blocked after the last valid data have been transferred, which means that all the data transferred to the RAM can be considered as valid.

At the end of the last DMA transfer (number of transfers configured in the DMA controller's DMA\_SxRTR register):

- No new DMA request is issued to the DMA controller if the DDS bit is cleared to 0 in the ADC\_CR2 register (this avoids generating an overrun error). However the DMA bit is not cleared by hardware. It must be written to 0, then to 1 to start a new transfer.
- Requests can continue to be generated if the DDS bit is set to 1. This allows configuring the DMA in double-buffer circular mode.

### 9.11.2 Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the EOCS bit must be set in the ADC\_CR2 register for the EOC status

bit to be set at the end of each conversion, and not only at the end of the sequence. When  $EOCS = 1$ , overrun detection is automatically enabled. Thus, each time a conversion is complete, EOC is set and the ADC\_DR register can be read. The overrun management is the same as when the DMA is used.

### 9.11.3 Conversions without reading all the data

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). For that, the DMA must be disabled ( $DMA = 0$ ) and the EOC bit must be set at the end of a sequence only ( $EOCS = 0$ ). In this configuration no overrun error is reported if a conversion finishes when the result of the previous conversion has not been read.

### 9.11.4 Overrun detection

Overrun detection is always enabled. It takes place before the data are synchronized to the APB clock.

*Note:* Only regular channel conversions generate overrun errors.

At the end of a conversion, the result is stored into an intermediate buffer (in the ADC clock domain) until it is transferred to the data register (ADC\_DR, in the APB clock domain). If new data arrive before the previous data are transferred, the new data are lost and an overrun error is detected. The OVR bit is set in the ADC\_SR register and an interrupt is generated if the OVRIE bit is set.

This may occur in two cases:

- either the delay is not properly set with respect to the APB clock frequency (the delay is too short to synchronize the data), or
- the previous data could not be synchronized to the APB clock because the ADC\_DR register is not empty (when  $DMA=1$  or  $EOCS=1$ ). Indeed, in these modes, the contents of the ADC\_DR register cannot be overwritten and so the register always contains the last valid data. ADC\_DR is emptied by reading it or by clearing the EOC bit in the ADC\_SR register.

- Note:*
- 1 An overrun may happen to be detected just after clearing the DMA (or EOCs) when the last data transferred by the DMA are read very late, which causes the next data to be lost.
  - 2 After clearing the OVR bit, the software should not launch a new regular conversion until  $RCNR=0$  in the ADC\_SR register.

## 9.12 Temperature sensor

The temperature sensor can be used to measure the internal temperature of the device. It is internally connected to the ADC TS (ADC channel 16: temperature sensor) input channel that is used to convert the sensor output voltage into a digital value.

*Note:* When it is not used, this sensor can be put in power-down mode.

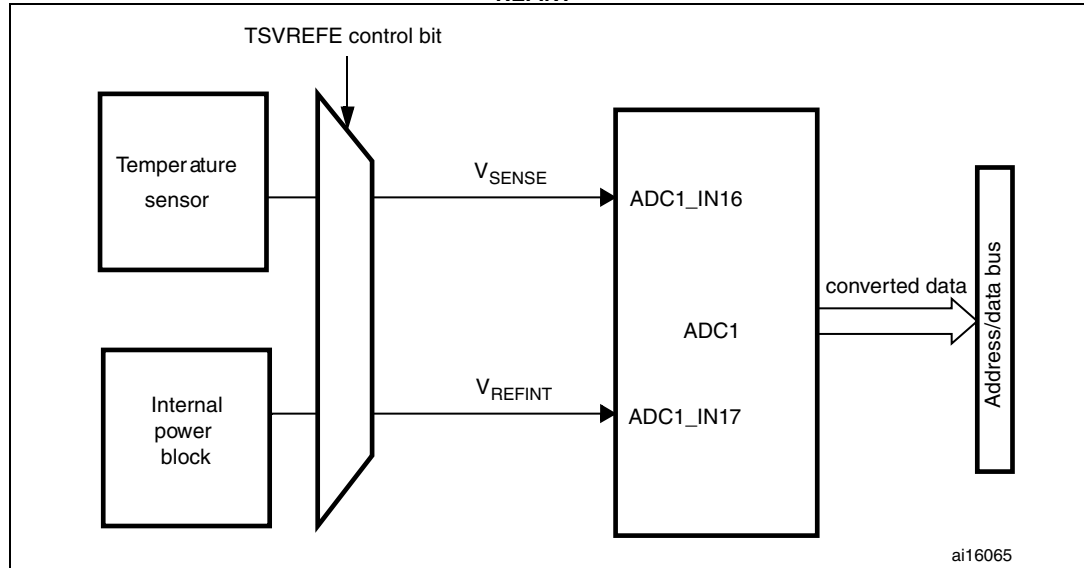

*Note:* The TSVREFE bit must be set to enable the conversion of both internal channels: ADC channel 16 (temperature sensor) and ADC channel 17 (VREFINT). If the temperature sensor conversion is required, this connection must be enabled.

The internal temperature sensor can also be used to detect temperature variations.

The temperature sensor is factory measured at high temperature and the result of the ADC conversion is stored in a specific data address : the TS\_Factory\_CONV\_V90 data (result of the factory TS voltage conversion at 90°C; refer to the device datasheet for more details).

To reduce the temperature sensor error, the user can measure it at ambient temperature (25°C) to redefine more accurately the average slope (avg\_slope) and the offset.

**Figure 39. Temperature sensor and V<sub>REFINT</sub> channel block diagram**

### 9.12.1 How to read the temperature

To read the temperature from the sensor, use the following procedure:

1. Select the ADC TS (temperature sensor) input channel.
2. Select a sample time of 10 μs.
3. Set the TSVREFE bit in the ADC\_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting VSENSE data in the ADC data register.
6. Calculate the temperature using the following formulae:

$$T[^\circ\text{K}] = \frac{V_{\text{SENSE}}}{\text{AvgSlope}}$$

$$T[^\circ\text{C}] = \frac{V_{\text{SENSE}}}{\text{AvgSlope}} - 273.15$$

Avg\_Slope = average slope of the "Temperature vs. VSENSE" curves (given in mV/°C).

Refer to the Electrical characteristics section for the Avg\_Slope value.

*Note:* When the sensor wakes up from power-down mode, a stabilization time is required before a correct voltage can be output.

After power-on, the ADC also needs a stabilization time. To minimize this delay, the ADON and TSON bits should be set at the same time.

### 9.13 Internal reference voltage ( $V_{REFINT}$ ) conversion

The internal reference voltage is internally connected to the VREFINT channel. This analog input channel is used to convert the internal reference voltage into a digital value.

The TSVREFE bit in the ADC\_CCR register must be set to enable the internal reference voltage (and also the Temperature sensor). This reference voltage must be enabled only if its conversion is required.

The internal reference voltage is factory measured and the result of the ADC conversion is stored in a specific data address : the VREFINT\_Factory\_CONV byte.

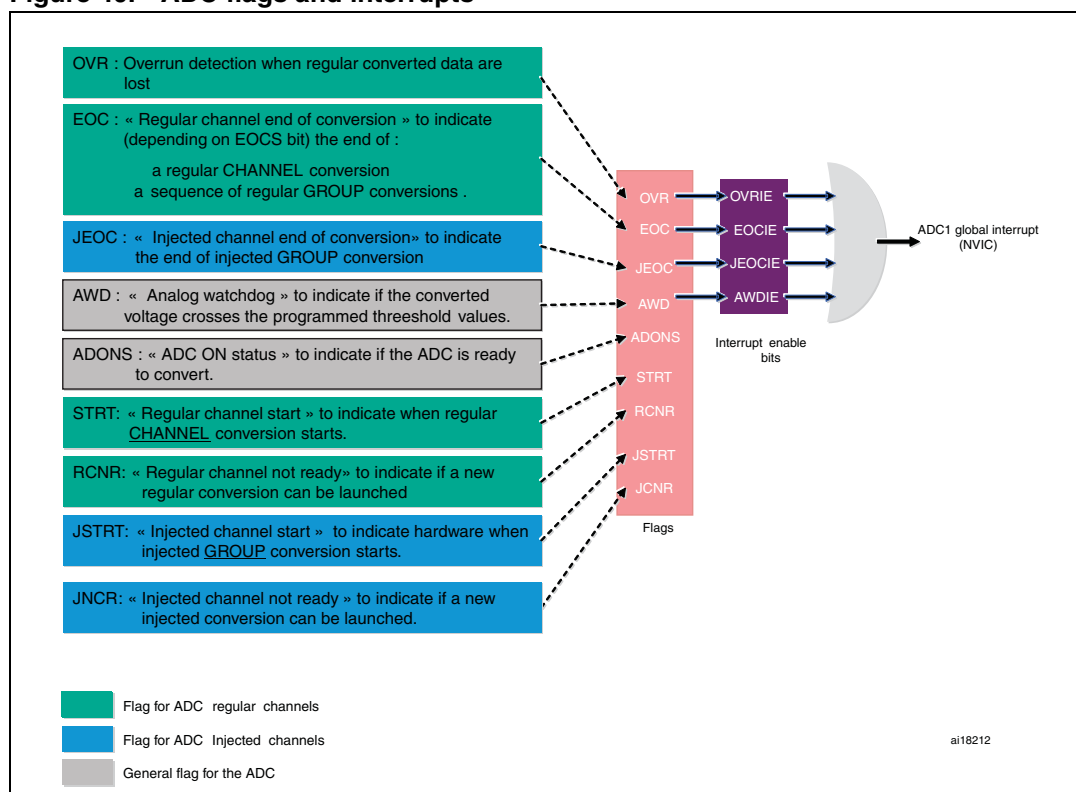

### 9.14 ADC interrupts

An interrupt can be produced on the end of conversion for regular and injected groups, when the analog watchdog status bit is set and when the overrun status bit is set. Separate interrupt enable bits are available for flexibility.

Five other flags are present in the ADC\_SR register, but there is no interrupt associated with them:

- JCNr (injected channel not ready)
- RCNR (regular channel not ready)
- ADONS (ADON status)
- JSTRT (Start of conversion for channels of an injected group)
- STRT (Start of conversion for channels of a regular group)

Figure 40. ADC flags and interrupts

**Table 39. ADC interrupts**

Interrupt event	Event flag	Enable control bit
End of conversion of a regular group	EOC	EOCIE
End of conversion of an injected group	JEOC	JEOCIE
Analog watchdog status bit is set	AWD	AWDIE
Overrun	OVR	OVRIE

## 9.15 ADC registers

Refer to [Section 1.1 on page 29](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

### 9.15.1 ADC status register (ADC\_SR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						JCNR	RCNR	Reserv ed	ADONS	OVR	STRT	JSTRT	JEOC	EOC	AWD
						r	r		r	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0

Bits 31:10 Reserved, must be kept cleared.

Bit 9 **JCNR**: Injected channel not ready

This bit is set and cleared by hardware after the JSQR register is written. It indicates if a new injected conversion can be launched (by setting the JSWSTART bit).

0: Injected channel ready

1: Injected channel not ready, JSWSTART must not be set

Bit 8 **RCNR**: Regular channel not ready

This bit is set and cleared by hardware after one of the SQRx register is written or after the OVR bit is cleared. It indicates if a new regular conversion can be launched (by setting the SWSTART bit).

0: Regular channel ready

1: Regular channel not ready, SWSTART must not be set

Bit 7 Reserved, must be kept cleared.

Bit 6 **ADONS**: ADC ON status

This bit is set and cleared by hardware to indicate if the ADC is ready to convert.

0: The ADC is not ready

1: The ADC is ready to convert. External triggers can be enabled, the SWSTART and JSWSTART bits can be set.

**Bit 5 OVR:** Overrun

This bit is set by hardware when regular conversion data are lost. It is cleared by software. Overrun detection is enabled only when DMA = 1 or EOCS = 1.

0: No overrun occurred  
1: Overrun has occurred

**Bit 4 STRT:** Regular channel start flag

This bit is set by hardware when regular channel conversion starts. It is cleared by software.

0: No regular channel conversion started  
1: Regular channel conversion has started

**Bit 3 JSTRT:** Injected channel start flag

This bit is set by hardware when injected group conversion starts. It is cleared by software.

0: No injected group conversion started  
1: Injected group conversion has started

**Bit 2 JEOC:** Injected channel end of conversion

This bit is set by hardware at the end of the conversion of all injected channels in the group. It is cleared by software.

0: Conversion is not complete  
1: Conversion complete

**Bit 1 EOC:** Regular channel end of conversion

This bit is set by hardware at the end of the conversion of a regular group of channels. It is cleared by software or by reading the ADC\_DR register.

0: Conversion not complete (EOCS=0), or sequence of conversions not complete (EOCS=1)  
1: Conversion complete (EOCS=0), or sequence of conversions complete (EOCS=1)

**Bit 0 AWD:** Analog watchdog flag

This bit is set by hardware when the converted voltage crosses the values programmed in the ADC\_LTR and ADC\_HTR registers. It is cleared by software.

0: No analog watchdog event occurred  
1: Analog watchdog event occurred

### 9.15.2 ADC control register 1 (ADC\_CR1)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Reserved					OVRIE	RES[1:0]		AWDEN	JAWDEN	Reserved					PDI	PDD
					rw	rw	rw	rw	rw						rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
DISCNUM[2:0]			JDISCEN	DISCEN	JAUTO	AWDSGL	SCAN	JEOCIE	AWDIE	EOCIE	AWDCH[4:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:27 Reserved, must be kept cleared.

Bit 26 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Bits 25:24 **RES[1:0]**: Resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit (  $T_{CONV} = 12 \text{ ADCCLK cycles}$  )

01: 10-bit (  $T_{CONV} = 11 \text{ ADCCLK cycles}$  )

10: 8-bit (  $T_{CONV} = 9 \text{ ADCCLK cycles}$  )

11: 6-bit (  $T_{CONV} = 7 \text{ ADCCLK cycles}$  )

*This bit must be written only when ADON=0.*

Bit 23 **AWDEN**: Analog watchdog enable on regular channels

This bit is set and cleared by software.

0: Analog watchdog disabled on regular channels

1: Analog watchdog enabled on regular channels

Bit 22 **JAWDEN**: Analog watchdog enable on injected channels

This bit is set and cleared by software.

0: Analog watchdog disabled on injected channels

1: Analog watchdog enabled on injected channels

Bits 21:18 Reserved, must be kept cleared.

Bit 17 **PDI**: Power down during the idle phase

This bit is written and cleared by software. When ADON=1, it determines whether the ADC is powered up or down when not converting (waiting for a hardware or software trigger event).

0: The ADC is powered up when waiting for a start event

1: The ADC is powered down when waiting for a start event

*Note: This bit must be written only when ADON=0.*

Bit 16 **PDD**: Power down during the delay phase

This bit is written and cleared by software. When ADON=1, it determines whether the ADC is powered up or down between 2 conversions (or sequences of conversions) when a delay is inserted (DELS bits).

0: The ADC is powered up during the delay

1: The ADC is powered down during the delay

*Note: This bit must be written only when ADON=0.*

- Bits 15:13 **DISCNUM[2:0]**: Discontinuous mode channel count  
These bits are written by software to define the number of channels to be converted in discontinuous mode, after receiving an external trigger.  
000: 1 channel  
001: 2 channels  
...  
111: 8 channels  
*Note: This bit must be written only when ADON=0.*
- Bit 12 **JDISEN**: Discontinuous mode on injected channels  
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.  
0: Discontinuous mode on injected channels disabled  
1: Discontinuous mode on injected channels enabled  
*Note: This bit must be written only when ADON=0.*
- Bit 11 **DISEN**: Discontinuous mode on regular channels  
This bit is set and cleared by software to enable/disable Discontinuous mode on regular channels.  
0: Discontinuous mode on regular channels disabled  
1: Discontinuous mode on regular channels enabled  
*Note: This bit must be written only when ADON=0.*
- Bit 10 **JAUTO**: Automatic injected group conversion  
This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.  
0: Automatic injected group conversion disabled  
1: Automatic injected group conversion enabled  
*Note: This bit must be written only when ADON=0.*
- Bit 9 **AWDSGL**: Enable the watchdog on a single channel in scan mode  
This bit is set and cleared by software to enable/disable the analog watchdog on the channel identified by the AWDCH[4:0] bits.  
0: Analog watchdog enabled on all channels  
1: Analog watchdog enabled on a single channel
- Bit 8 **SCAN**: Scan mode  
This bit is set and cleared by software to enable/disable the Scan mode. In the Scan mode, the inputs selected through the ADC\_SQRx or ADC\_JSQRx registers are converted.  
0: Scan mode disabled  
1: Scan mode enabled  
*Note: This bit must be written only when ADON=0.*
- Bit 7 **JEOCIE**: Interrupt enable for injected channels  
This bit is set and cleared by software to enable/disable the end of conversion interrupt for injected channels.  
0: JEOC interrupt disabled  
1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Bit 6 **AWDIE**: Analog watchdog interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog interrupt. In Scan mode if the watchdog thresholds are crossed, scan is aborted only if this bit is enabled.  
 0: Analog watchdog interrupt disabled  
 1: Analog watchdog interrupt enabled

Bit 5 **EOCIE**: Interrupt enable for EOC

This bit is set and cleared by software to enable/disable the end of conversion interrupt.  
 0: EOC interrupt disabled  
 1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Bits 4:0 **AWDCH[4:0]**: Analog watchdog channel select bits

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.  
 00000: ADC analog input Channel0  
 00001: ADC analog input Channel1  
 ...

11000: ADC analog input Channel24  
 11001: ADC analog input Channel25  
 11010: ADC analog input Channel26  
 Other values reserved.

*Note: ADC1 analog inputs Channel16, Channel 17 and Channel26 are internally connected to the temperature sensor, to V<sub>REFINT</sub> and to V<sub>COMP</sub> respectively.*

### 9.15.3 ADC control register 2 (ADC\_CR2)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
Reserv ed	SWST ART	EXTEN			EXTSEL[3:0]				Reserv ed	JSWST ART	JEXTEN			JEXTSEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Reserved				ALIGN	EOCS	DDS	DMA	Res.	DELS			Reserved		CONT	ADON		
				rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		

Bit 31 Reserved, must be kept cleared.

Bit 30 **SWSTART**: Start conversion of regular channels

This bit is set by software to start conversion and cleared by hardware as soon as the conversion starts.

0: Reset state  
 1: Starts conversion of regular channels

*Note: This bit must be set only when ADONS=1 and RCNR=0.*

Bits 29:28 **EXTEN**: External trigger enable for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Trigger detection disabled

01: Trigger detection on the rising edge

10: Trigger detection on the falling edge

11: Trigger detection on both the rising and falling edges

*Note: The external trigger must be enabled only when ADONS=1.*

Bits 27:24 **EXTSEL[3:0]**: External event select for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

0000: TIM9\_CC2 event

0001: TIM9\_TRGO event

0010: TIM2\_CC3 event

0011: TIM2\_CC2 event

0100: TIM3\_TRGO event

0101: TIM4\_CC4 event

0110: TIM2\_TRGO event

0111: TIM3\_CC1 event

1000: TIM3\_CC3 event

1001: TIM4\_TRGO event

1010: TIM6\_TRGO event

1011: Reserved

1100: Reserved

1101: Reserved

1110: Reserved

1111: EXTI line11

Bit 23 Reserved, must be kept cleared.

Bit 22 **JSWSTART**: Start conversion of injected channels

This bit is set by software and cleared by hardware as soon as the conversion starts.

0: Reset state

1: Starts conversion of injected channels

*Note: This bit must be set only when ADONS=1 and JCNR=0.*

Bits 21:20 **JEXTEN**: External trigger enable for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Trigger detection disabled

01: Trigger detection on the rising edge

10: Trigger detection on the falling edge

11: Trigger detection on both the rising and falling edges

*Note: The external trigger must be enabled only when ADONS=1.*

Bits 19:16 **JEXTSEL[3:0]**: External event select for injected group

These bits select the external event used to trigger the start of conversion of an injected group.

0000: TIM9\_CC1 event  
0001: TIM9\_TRGO event  
0010: TIM2\_TRGO event  
0011: TIM2\_CC1 event  
0100: TIM3\_CC4 event  
0101: TIM4\_TRGO event  
0110: TIM4\_CC1 event  
0111: TIM4\_CC2 event  
1000: TIM4\_CC3 event  
1001: TIM10\_CC1 event  
1010: TIM7\_TRGO event  
1011: Reserved  
1100: Reserved  
1101: Reserved  
1110: Reserved  
1111: EXTI line15

Bits 15:12 Reserved, must be kept cleared.

Bit 11 **ALIGN**: Data alignment

This bit is set and cleared by software. Refer to [Figure 30](#) and [Figure 31](#).

0: Right alignment  
1: Left alignment

Bit 10 **EOCS**: End of conversion selection

This bit is set and cleared by software.

0: The EOC bit is set at the end of each sequence of regular conversions  
1: The EOC bit is set at the end of each regular conversion

Bit 9 **DDS**: DMA disable selection

This bit is set and cleared by software.

0: No new DMA request is issued after the last transfer (as configured in the DMA controller)  
1: DMA requests are issued as long as data are converted and DMA=1

Bit 8 **DMA**: Direct memory access mode

This bit is set and cleared by software. Refer to the DMA controller chapter for more details.

0: DMA mode disabled  
1: DMA mode enabled

Bit 7 Reserved, must be kept cleared.

Bit 6:4 **DELS**: Delay selection

These bits are set and cleared by software. They define the length of the delay which is applied after a conversion or a sequence of conversions.

000: No delay

001: Until the converted data have been read (DR read or EOC=0 for regular conversions, JEOC=0 for injected conversions)

010: 7 APB clock cycles after the end of conversion

011: 15 APB clock cycles after the end of conversion

100: 31 APB clock cycles after the end of conversion

101: 63 APB clock cycles after the end of conversion

110: 127 APB clock cycles after the end of conversion

111: 255 APB clock cycles after the end of conversion

*Note:* 1- This bit must be written only when ADON=0.

2- Due to clock domain crossing, a latency of 2 or 3 ADC clock cycles is added to the delay before a new conversion can start.

3- The delay required for a given frequency ratio between the APB clock and the ADC clock depends on the activity on the AHB and APB busses. If the ADC is the only peripheral that needs to transfer data, then a minimum delay should be configured: 15 APB clock cycles if  $f_{APB} < f_{ADCCLK}/2$  or else 7 APB clock cycles if  $f_{APB} < f_{ADCCLK}$ , otherwise no delay is needed.

Bits 3:2 Reserved, must be kept cleared.

Bit 1 **CONT**: Continuous conversion

This bit is set and cleared by software. If it is set, conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Bit 0 **ADON**: A/D Converter ON / OFF

This bit is set and cleared by software.

0: Disable ADC conversion and go to power down mode

1: Enable ADC: conversions can start as soon as a start event (hardware or software) is received. When not converting, the ADC goes to the power up or power down mode depending on the PDI and PDD bits.

*Note:* This bit must be set only when ADONS=0 and cleared only when ADONS=1.

### 9.15.4 ADC sample time register 1 (ADC\_SMPR1)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept cleared.

Bits 29:0 **SMPx[2:0]**: Channel x Sample time selection

These bits are written by software to select the sampling time individually for each channel. During the sampling cycles, the channel selection bits must remain unchanged.

- 000: 4 cycles
- 001: 9 cycles
- 010: 16 cycles
- 011: 24 cycles
- 100: 48 cycles
- 101: 96 cycles
- 110: 192 cycles
- 111: 384 cycles

*Note: These bits must be written only when ADON=0.*

### 9.15.7 ADC injected channel data offset register x (ADC\_JOFRx)(x=1..4)

Address offset: 0x18-0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				JOFFSETx[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept cleared.

Bits 11:0 **JOFFSETx[11:0]**: Data offset for injected channel x

These bits are written by software to define the offset to be subtracted from the raw converted data when converting injected channels. The conversion result can be read from in the ADC\_JDRx registers.

### 9.15.8 ADC watchdog higher threshold register (ADC\_HTR)

Address offset: 0x28

Reset value: 0x0000 0FFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				HT[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept cleared.

Bits 11:0 **HT[11:0]**: Analog watchdog higher threshold

These bits are written by software to define the higher threshold for the analog watchdog.

### 9.15.9 ADC watchdog lower threshold register (ADC\_LTR)

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				LT[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept cleared.

Bits 11:0 **LT[11:0]**: Analog watchdog lower threshold

These bits are written by software to define the lower threshold for the analog watchdog.

### 9.15.10 ADC regular sequence register 1 (ADC\_SQR1)

Address offset: 0x30

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Reserved							L[4:0]					Reserved			
								rw	rw	rw	rw	rw				
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserv- ed	SQ27[4:0]					SQ26[4:0]					SQ25[4:0]					
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:25 Reserved, must be kept cleared.

Bits 24:20 **L[4:0]**: Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

00000: 1 conversion

00001: 2 conversions

...

11010: 27 conversions

Bits 19:15 Reserved, must be kept cleared.

Bits 14:10 **SQ27[4:0]**: 27th conversion in regular sequence

These bits are written by software with the channel number (0..26) assigned as the 27th in the conversion sequence.

Bits 9:5 **SQ26[4:0]**: 26th conversion in regular sequence

Bits 4:0 **SQ25[4:0]**: 25th conversion in regular sequence

### 9.15.11 ADC regular sequence register 2 (ADC\_SQR2)

Address offset: 0x34

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Reserved		SQ24[4:0]					SQ23[4:0]					SQ22[4:1]			
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SQ22[0]	SQ21[4:0]					SQ20[4:0]					SQ19[4:0]				
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:30 Reserved, must be kept cleared.

Bits 29:26 **SQ24[4:0]**: 24th conversion in regular sequence

These bits are written by software with the channel number (0..26) assigned as the 24th in the sequence to be converted.

Bits 24:20 **SQ23[4:0]**: 23rd conversion in regular sequence

Bits 19:15 **SQ22[4:0]**: 22nd conversion in regular sequence

- Bits 14:10 **SQ21[4:0]**: 21st conversion in regular sequence
- Bits 9:5 **SQ20[4:0]**: 20th conversion in regular sequence
- Bits 4:0 **SQ19[4:0]**: 19th conversion in regular sequence

### 9.15.12 ADC regular sequence register 3 (ADC\_SQR3)

Address offset: 0x38

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
	Reserved				SQ18[4:0]					SQ17[4:0]					SQ16[4:1]			
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
	SQ16[0]	SQ15[4:0]					SQ14[4:0]					SQ13[4:0]						

- Bits 31:30 Reserved, must be kept cleared.
- Bits 29:25 **SQ18[4:0]**: 18th conversion in regular sequence  
 These bits are written by software with the channel number (0..26) assigned as the 18th in the sequence to be converted.
- Bits 24:20 **SQ17[4:0]**: 17th conversion in regular sequence
- Bits 19:15 **SQ16[4:0]**: 16th conversion in regular sequence
- Bits 14:10 **SQ15[4:0]**: 15th conversion in regular sequence
- Bits 9:5 **SQ14[4:0]**: 14th conversion in regular sequence
- Bits 4:0 **SQ13[4:0]**: 13th conversion in regular sequence

### 9.15.13 ADC regular sequence register 4 (ADC\_SQR4)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved		SQ12[4:0]					SQ11[4:0]					SQ10[4:1]			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ10[0]		SQ9[4:0]					SQ8[4:0]					SQ7[4:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept cleared.

Bits 29:26 **SQ12[4:0]**: 12th conversion in regular sequence

These bits are written by software with the channel number (0..26) assigned as the 12th in the sequence to be converted.

Bits 24:20 **SQ11[4:0]**: 11th conversion in regular sequence

Bits 19:15 **SQ10[4:0]**: 10th conversion in regular sequence

Bits 14:10 **SQ9[4:0]**: 9th conversion in regular sequence

Bits 9:5 **SQ8[4:0]**: 8th conversion in regular sequence

Bits 4:0 **SQ7[4:0]**: 7th conversion in regular sequence

### 9.15.14 ADC regular sequence register 5 (ADC\_SQR5)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved		SQ6[4:0]					SQ5[4:0]					SQ4[4:1]			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ4_0		SQ3[4:0]					SQ2[4:0]					SQ1[4:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept cleared.

Bits 29:25 **SQ6[4:0]**: 6th conversion in regular sequence

These bits are written by software with the channel number (0..26) assigned as the 6th in the sequence to be converted.

Bits 24:20 **SQ5[4:0]**: 5th conversion in regular sequence

Bits 19:15 **SQ4[4:0]**: 4th conversion in regular sequence

Bits 14:10 **SQ3[4:0]**: 3rd conversion in regular sequence

Bits 9:5 **SQ2[4:0]**: 2nd conversion in regular sequence

Bits 4:0 **SQ1[4:0]**: 1st conversion in regular sequence

### 9.15.15 ADC injected sequence register (ADC\_JSQR)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved										JL[1:0]		JSQ4[4:1]			
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ4[0]		JSQ3[4:0]				JSQ2[4:0]				JSQ1[4:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept cleared.

Bits 21:20 **JL[1:0]**: Injected sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

- 00: 1 conversion
- 01: 2 conversions
- 10: 3 conversions
- 11: 4 conversions

Bits 19:15 **JSQ4[4:0]**: 4th conversion in injected sequence (when JL[1:0]=3, see note below)

These bits are written by software with the channel number (0..18) assigned as the 4th in the sequence to be converted.

Bits 14:10 **JSQ3[4:0]**: 3rd conversion in injected sequence (when JL[1:0]=3, see note below)

Bits 9:5 **JSQ2[4:0]**: 2nd conversion in injected sequence (when JL[1:0]=3, see note below)

Bits 4:0 **JSQ1[4:0]**: 1st conversion in injected sequence (when JL[1:0]=3, see note below)

*Note:* When JL[1:0]=3 (4 injected conversions in the sequencer), the ADC converts the channels in the following order: JSQ1[4:0], JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0].

When JL=2 (3 injected conversions in the sequencer), the ADC converts the channels in the following order: JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0].

When JL=1 (2 injected conversions in the sequencer), the ADC converts the channels in starting from JSQ3[4:0], and then JSQ4[4:0].

When JL=0 (1 injected conversion in the sequencer), the ADC converts only JSQ4[4:0] channel.

### 9.15.16 ADC injected data register x (ADC\_JDRx) (x= 1..4)

Address offset: 0x48 - 0x54

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept cleared.

Bits 15:0 **JDATA[15:0]**: Injected data

These bits are read-only. They contain the conversion result from injected channel x. The data are left -or right-aligned as shown in [Figure 30](#) and [Figure 31](#).

### 9.15.17 ADC regular data register (ADC\_DR)

Address offset: 0x58

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved.

Bits 15:0 **DATA[15:0]**: Regular data

These bits are read-only. They contain the conversion result from the regular channels. The data are left- or right-aligned as shown in [Figure 30](#) and [Figure 31](#).

### 9.15.18 ADC common status register (ADC\_CSR)

Address offset: 0x00 (this offset address is relative to the base address of ADC common registers, i.e. 0x300)

Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing it to 0 in the corresponding ADC\_SR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

										r	r	r	r	r	r	r

Bits 31:7 Reserved, must be kept cleared.

Bit 6 **ADONS1**: *ADON Status of ADC1*

This bit is a copy of the ADONS bit in the ADC\_SR register.

Bit 5 **OVR1**: Overrun flag of the ADC

This bit is a copy of the OVR bit in the ADC\_SR register.

Bit 4 **STRT1**: Regular channel Start flag of the ADC

This bit is a copy of the STRT bit in the ADC\_SR register.

- Bit 3 **JSTRT1**: Injected channel Start flag of the ADC  
This bit is a copy of the JSTRT bit in the ADC\_SR register.
- Bit 2 **JEOC1**: Injected channel end of conversion of the ADC  
This bit is a copy of the JEOC bit in the ADC\_SR register.
- Bit 1 **EOC1**: End of conversion of the ADC  
This bit is a copy of the EOC bit in the ADC\_SR register.
- Bit 0 **AWD1**: Analog watchdog flag of the ADC  
This bit is a copy of the AWD bit in the ADC\_SR register.

### 9.15.19 ADC common control register (ADC\_CCR)

Address offset: 0x04 (this offset address is relative to the base address of ADC common registers, i.e. 0x300)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								rw							rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved																

- Bits 31:24 Reserved, must be kept cleared.
- Bit 23 **TSVREFE**: Temperature sensor and  $V_{REFINT}$  enable  
This bit is set and cleared by software to enable/disable the temperature sensor and the  $V_{REFINT}$  channel.  
0: Temperature sensor and  $V_{REFINT}$  channel disabled  
1: Temperature sensor and  $V_{REFINT}$  channel enabled
- Bits 22:18 Reserved, must be kept cleared.
- Bits 17:16 **ADCPRE**: ADC prescaler  
Set and cleared by software to select the frequency of the clock to the ADC.  
00: HSI divided by 1  
01: HSI divided by 2  
10: HSI divided by 4  
11: Reserved
- Bits 15:0 Reserved, must be kept cleared.

### 9.15.20 ADC register map

The following table summarizes the ADC registers.

**Table 40. ADC global register map**

Offset	Register
0x000 - 0x058	ADC
0x05C - 0x2FC	Reserved
0x300 - 0x304	Common registers

**Table 41. ADC register map and reset values**

## 10 Digital-to-analog converter (DAC)

### 10.1 DAC introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC has two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin,  $V_{REF+}$  (shared with ADC) is available for better resolution.

### 10.2 DAC main features

- Two DAC converters: one output channel each
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave generation
- Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel
- DMA underrun error detection
- External triggers for conversion
- Input voltage reference,  $V_{REF+}$

[Figure 41](#) shows the block diagram of a DAC channel and [Table 43](#) gives the pin description.

Figure 41. DAC channel block diagram

Table 43. DAC pins

Name	Signal type	Remarks
V <sub>REF+</sub>	Input, analog reference positive	The higher/positive reference voltage for the DAC, $1.8\text{ V} \leq V_{\text{REF+}} \leq V_{\text{DDA}}$
V <sub>DDA</sub>	Input, analog supply	Analog power supply
V <sub>SSA</sub>	Input, analog supply ground	Ground for analog power supply
DAC_OUTx	Analog output signal	DAC channelx analog output

*Note:* Once the DAC channelx is enabled, the corresponding GPIO pin (PA4 or PA5) is automatically connected to the analog converter output (DAC\_OUTx). In order to avoid parasitic consumption, the PA4 or PA5 pin should first be configured to analog (AIN).

## 10.3 DAC functional description

### 10.3.1 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC\_CR register. The DAC channel is then enabled after a startup time  $t_{WAKEUP}$ .

*Note:* The ENx bit enables the analog DAC Channelx macrocell only. The DAC Channelx digital interface is enabled even if the ENx bit is reset.

### 10.3.2 DAC output buffer enable

The DAC integrates two output buffers that can be used to reduce the output impedance, and to drive external loads directly without having to add an external operational amplifier. Each DAC channel output buffer can be enabled and disabled using the corresponding BOFFx bit in the DAC\_CR register.

### 10.3.3 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channelx, there are three possibilities:
  - 8-bit right alignment: the software has to load data into the DAC\_DHR8Rx [7:0] bits (stored into the DHRx[11:4] bits)
  - 12-bit left alignment: the software has to load data into the DAC\_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
  - 12-bit right alignment: the software has to load data into the DAC\_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC\_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

**Figure 42. Data registers in single DAC channel mode**

- Dual DAC channels, there are three possibilities:
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC\_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC\_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC\_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

**Figure 43. Data registers in dual DAC channel mode**

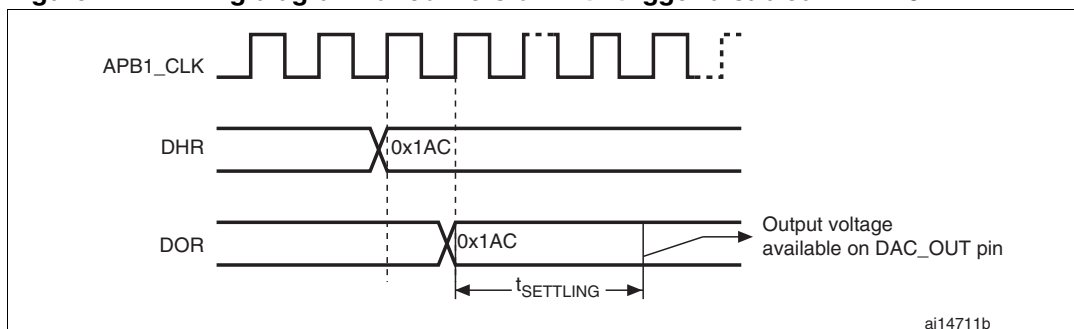

### 10.3.4 DAC conversion

The DAC\_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC\_DHRx register (write to DAC\_DHR8Rx, DAC\_DHR12Lx, DAC\_DHR12Rx, DAC\_DHR8RD, DAC\_DHR12LD or DAC\_DHR12LD).

Data stored in the DAC\_DHRx register are automatically transferred to the DAC\_DORx register after one APB1 clock cycle, if no hardware trigger is selected (TENx bit in DAC\_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC\_CR register is set) and a trigger occurs, the transfer is performed three APB1 clock cycles later.

When DAC\_DORx is loaded with the DAC\_DHRx contents, the analog output voltage becomes available after a time  $t_{SETTLING}$  that depends on the power supply voltage and the analog output load.

**Figure 44. Timing diagram for conversion with trigger disabled TEN = 0**

### 10.3.5 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and  $V_{REF+}$ .

The analog output voltages on each DAC channel pin are determined by the following equation:

$$DAC_{output} = V_{REF} \times \frac{DOR}{4095}$$

### 10.3.6 DAC trigger selection

If the TENx control bit is set, conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[2:0] control bits determine which out of 8 possible events will trigger conversion as shown in [Table 44](#).

**Table 44. External triggers**

Source	Type	TSEL[2:0]
Timer 6 TRGO event	Internal signal from on-chip timers	000
Reserved		001
Timer 7 TRGO event		010
Timer 9 TRGO event		011
Timer 2 TRGO event		100
Timer 4 TRGO event		101
EXTI line9	External pin	110
SWTRIG	Software control bit	111

Each time a DAC interface detects a rising edge on the selected timer TRGO output, or on the selected external interrupt line 9, the last data stored into the DAC\_DHRx register are transferred into the DAC\_DORx register. The DAC\_DORx register is updated three APB1 cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC\_DORx register has been loaded with the DAC\_DHRx register contents.

- Note:*
- 1 *TSELx[2:0] bit cannot be changed when the ENx bit is set.*
  - 2 *When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DORx register takes only one APB1 clock cycle.*

### 10.3.7 DMA request

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

A DAC DMA request is generated when an external trigger (but not a software trigger) occurs while the DMAENx bit is set. The value of the DAC\_DHRx register is then transferred into the DAC\_DORx register.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, you should set only the corresponding DMAENx bit. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

### DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgement for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC\_SR register is set, reporting the error condition. DMA data transfers are then disabled and no further DMA request is treated. The DAC channelx continues to convert old data.

The software should clear the DMAUDRx flag by writing “1”, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software should modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC\_CR register is enabled.

### 10.3.8 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to “01”. The preloaded value in LFSR is 0xAAA. This register is updated three APB1 clock cycles after each trigger event, following a specific calculation algorithm.

Figure 45. DAC LFSR register calculation algorithm

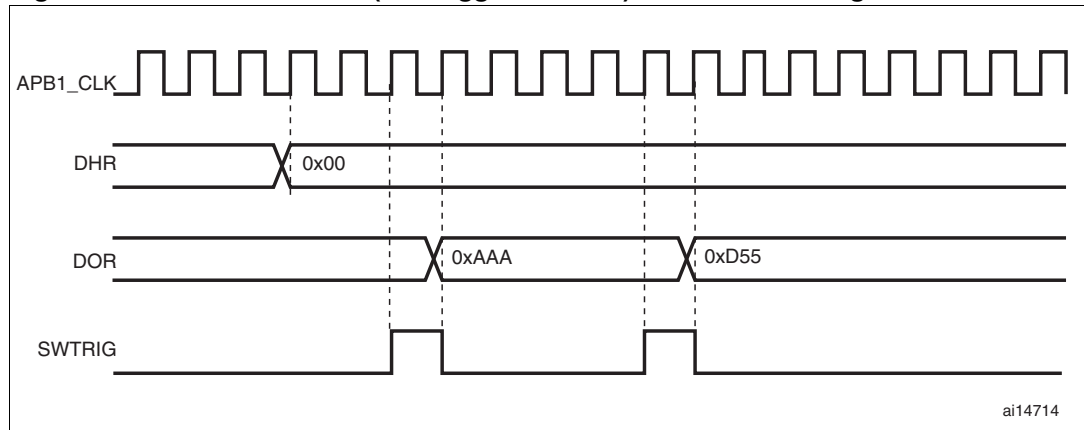

The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC\_CR register, is added up to the DAC\_DHRx contents without overflow and this value is then stored into the DAC\_DORx register.

If LFSR is 0x0000, a ‘1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

**Figure 46. DAC conversion (SW trigger enabled) with LFSR wave generation**

*Note:* The DAC trigger must be enabled for noise generation by setting the *TENx* bit in the *DAC\_CR* register.

### 10.3.9 Triangle-wave generation

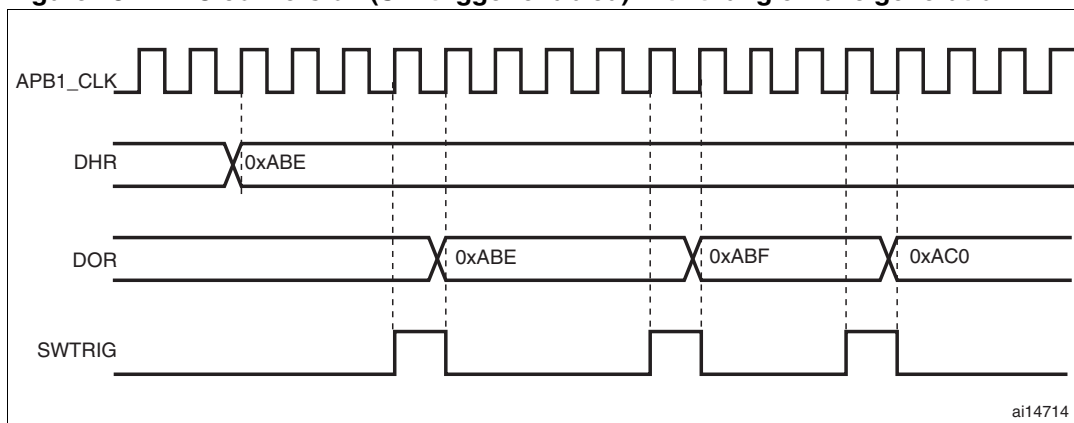

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting *WAVEx*[1:0] to “10”. The amplitude is configured through the *MAMPx*[3:0] bits in the *DAC\_CR* register. An internal triangle counter is incremented three APB1 clock cycles after each trigger event. The value of this counter is then added to the *DAC\_DHRx* register without overflow and the sum is stored into the *DAC\_DORx* register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the *MAMPx*[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the *WAVEx*[1:0] bits.

**Figure 47. DAC triangle wave generation**

**Figure 48. DAC conversion (SW trigger enabled) with triangle wave generation**

- Note:*
- 1 The DAC trigger must be enabled for noise generation by setting the *TENx* bit in the *DAC\_CR* register.
  - 2 The *MAMPx[3:0]* bits must be configured before enabling the DAC, otherwise they cannot be changed.

## 10.4 Dual DAC channel conversion

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time.

Eleven possible conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

### 10.4.1 Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits *TEN1* and *TEN2*
- Configure different trigger sources by setting different values in the *TSEL1[2:0]* and *TSEL2[2:0]* bits
- Load the dual DAC channel data into the desired DHR register (*DAC\_DHR12RD*, *DAC\_DHR12LD* or *DAC\_DHR8RD*)

When a DAC channel1 trigger arrives, the DHR1 register is transferred into *DAC\_DOR1* (three APB1 clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into *DAC\_DOR2* (three APB1 clock cycles later).

### 10.4.2 Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

### 10.4.3 Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

### 10.4.4 Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into

DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

#### 10.4.5 Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

#### 10.4.6 Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

In this configuration, one APB1 clock cycle later, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively.

#### 10.4.7 Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively (after three APB1 clock cycles).

#### 10.4.8 Simultaneous trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

#### 10.4.9 Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated.

At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

#### 10.4.10 Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value using the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is

added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

### 10.4.11 Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the DAC channel2 triangle counter is updated.

## 10.5 DAC registers

Refer to [Section 1.1 on page 29](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

### 10.5.1 DAC control register (DAC\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved		DMAU DRIE2	DMA EN2	MAMP2[3:0]				WAVE2[1:0]		TSEL2[2:0]			TEN2	BOFF2	EN2
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		DMAU DRIE1	DMA EN1	MAMP1[3:0]				WAVE1[1:0]		TSEL1[2:0]			TEN1	BOFF1	EN1
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved.

Bits 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled

1: DAC channel2 DMA mode enabled

Bit 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1  
 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
 ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bit 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled  
 01: Noise wave generation enabled  
 1x: Triangle wave generation enabled

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)*

Bits 21:19 **TSEL2[2:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

000: Timer 6 TRGO event  
 001: Reserved  
 010: Timer 7 TRGO event  
 011: Timer 9 TRGO event  
 100: Timer 2 TRGO event  
 101: Timer 4 TRGO event  
 110: External line9  
 111: Software trigger

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).*

Bit 18 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC\_DHRx register are transferred one APB1 clock cycle later to the DAC\_DOR2 register  
 1: DAC channel2 trigger enabled and data from the DAC\_DHRx register are transferred three APB1 clock cycles later to the DAC\_DOR2 register

*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR2 register takes only one APB1 clock cycle.*

Bit 17 **BOFF2**: DAC channel2 output buffer disable

This bit is set and cleared by software to enable/disable DAC channel2 output buffer.

0: DAC channel2 output buffer enabled  
 1: DAC channel2 output buffer disabled

Bit 16 **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.

0: DAC channel2 disabled  
 1: DAC channel2 enabled

Bits 15:14 Reserved.

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1

0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3

0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7

0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15

0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31

0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63

0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127

0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255

1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511

1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023

1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047

≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.

00: wave generation disabled

01: Noise wave generation enabled

1x: Triangle wave generation enabled

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bits 5:3 **TSEL1[2:0]**: DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1.

000: Timer 6 TRGO event

001: Reserved

010: Timer 7 TRGO event

011: Timer 9 TRGO event

100: Timer 2 TRGO event

101: Timer 4 TRGO event

110: External line9

111: Software trigger

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

- Bit 2 **TEN1**: DAC channel1 trigger enable  
 This bit is set and cleared by software to enable/disable DAC channel1 trigger.  
 0: DAC channel1 trigger disabled and data written into the DAC\_DHRx register are transferred one APB1 clock cycle later to the DAC\_DOR1 register  
 1: DAC channel1 trigger enabled and data from the DAC\_DHRx register are transferred three APB1 clock cycles later to the DAC\_DOR1 register  
*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR1 register takes only one APB1 clock cycle.*
- Bit 1 **BOFF1**: DAC channel1 output buffer disable  
 This bit is set and cleared by software to enable/disable DAC channel1 output buffer.  
 0: DAC channel1 output buffer enabled  
 1: DAC channel1 output buffer disabled
- Bit 0 **EN1**: DAC channel1 enable  
 This bit is set and cleared by software to enable/disable DAC channel1.  
 0: DAC channel1 disabled  
 1: DAC channel1 enabled

Refer to [Table 1 on page 32](#) for the register boundary addresses.

# 11 Comparators (COMP)

## 11.1 Introduction

The STM32L15xxx contains two zero-crossing comparators COMP1 and COMP2, that share the same current bias.

*Note:* For all I/Os used as comparator inputs, the GPIO registers must be configured in analog mode.

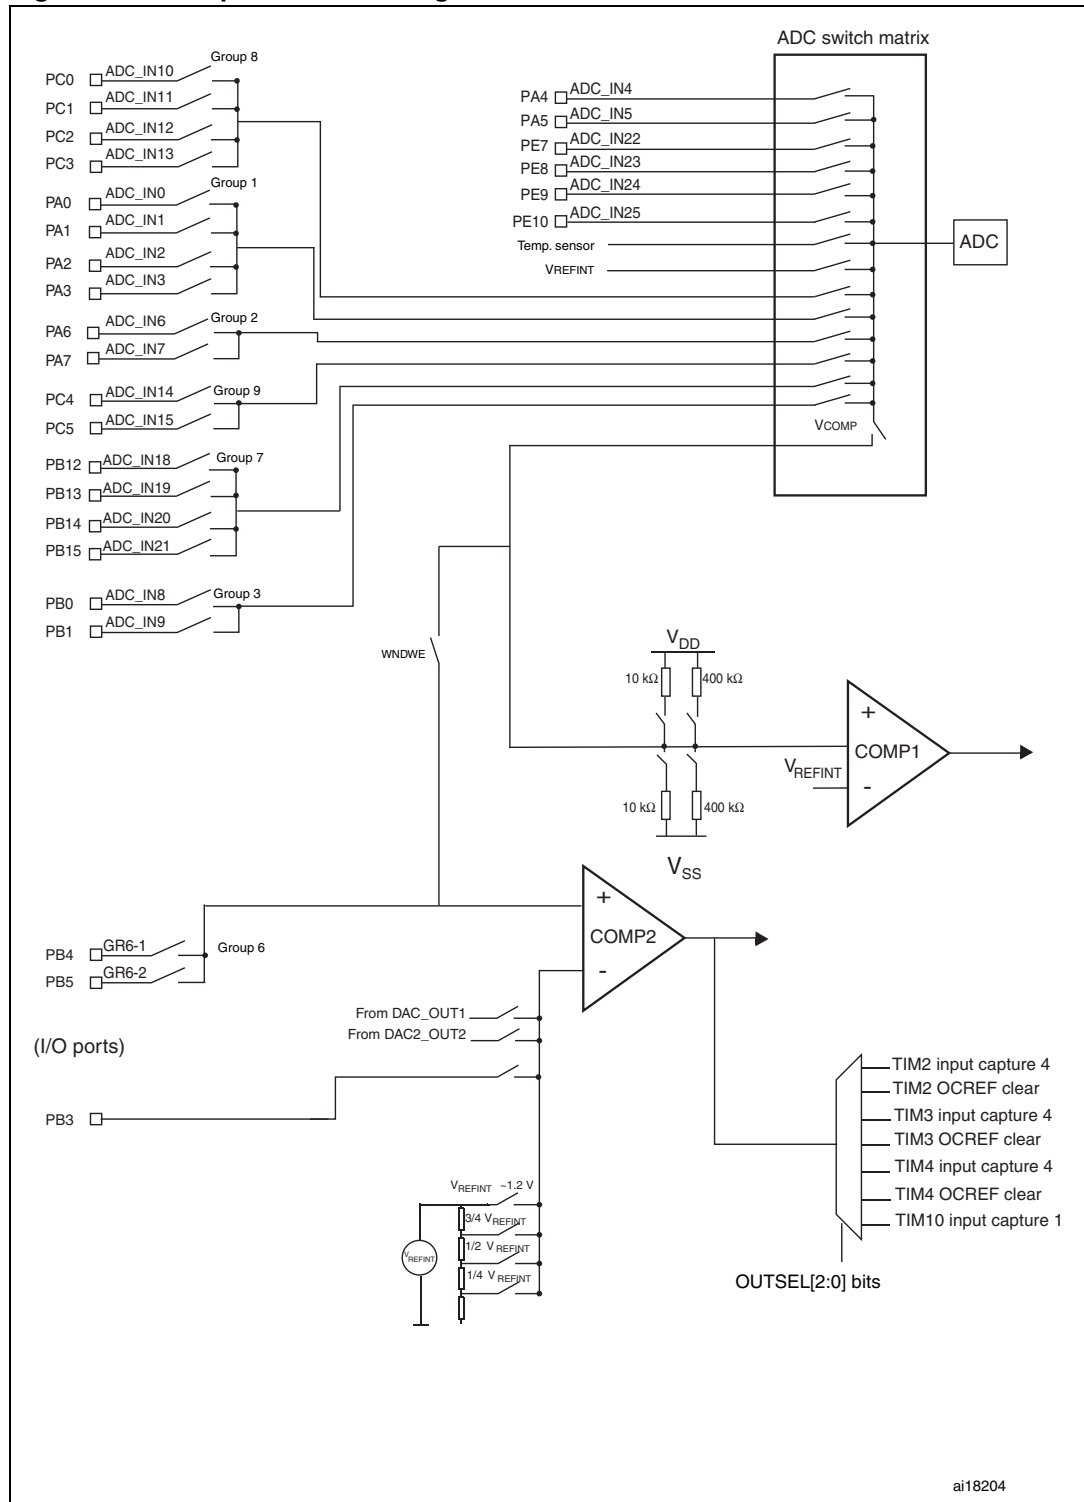

When using the routing interface (see [Section 6: System configuration controller \(SYSCFG\) and routing interface \(RI\)](#)), the comparator inputs can be connected to external I/Os.

## 11.2 Main features

- A comparator (COMP1) with fixed threshold (internal reference voltage). The non-inverting input can be selected among 24 external I/Os.
- A rail-to-rail comparator (COMP2) with selectable threshold. The non-inverting input can be selected among 2 I/Os. The threshold can be selected among:
  - the internal reference voltage ( $V_{REFINT}$ )
  - an internal reference voltage submultiple (1/4, 1/2, 3/4)
  - the DAC1 output
  - the DAC2 output
  - an external I/O (PB3)
- The 2 comparators can be combined to form window comparators.
- Zero-crossing can generate a rising or falling edge on the comparator outputs depending on the trigger configuration.
- Each comparator has an interrupt generation capability with wakeup from the Sleep and Stop.
- The COMP2 output can be redirected to TIM2/TIM3/TIM4's input capture 4 (IC4) or OCREF\_CLR inputs, or to the TIM10s input capture 1 (IC1).
- COMP2 speed is configurable for optimum speed/consumption ratio.

The block diagram of the COMP is shown in [Figure 49](#).

Figure 49. Comparator block diagram

Note: The internal reference voltage and temperature sensor cannot be used as COMP1 non-inverting input.

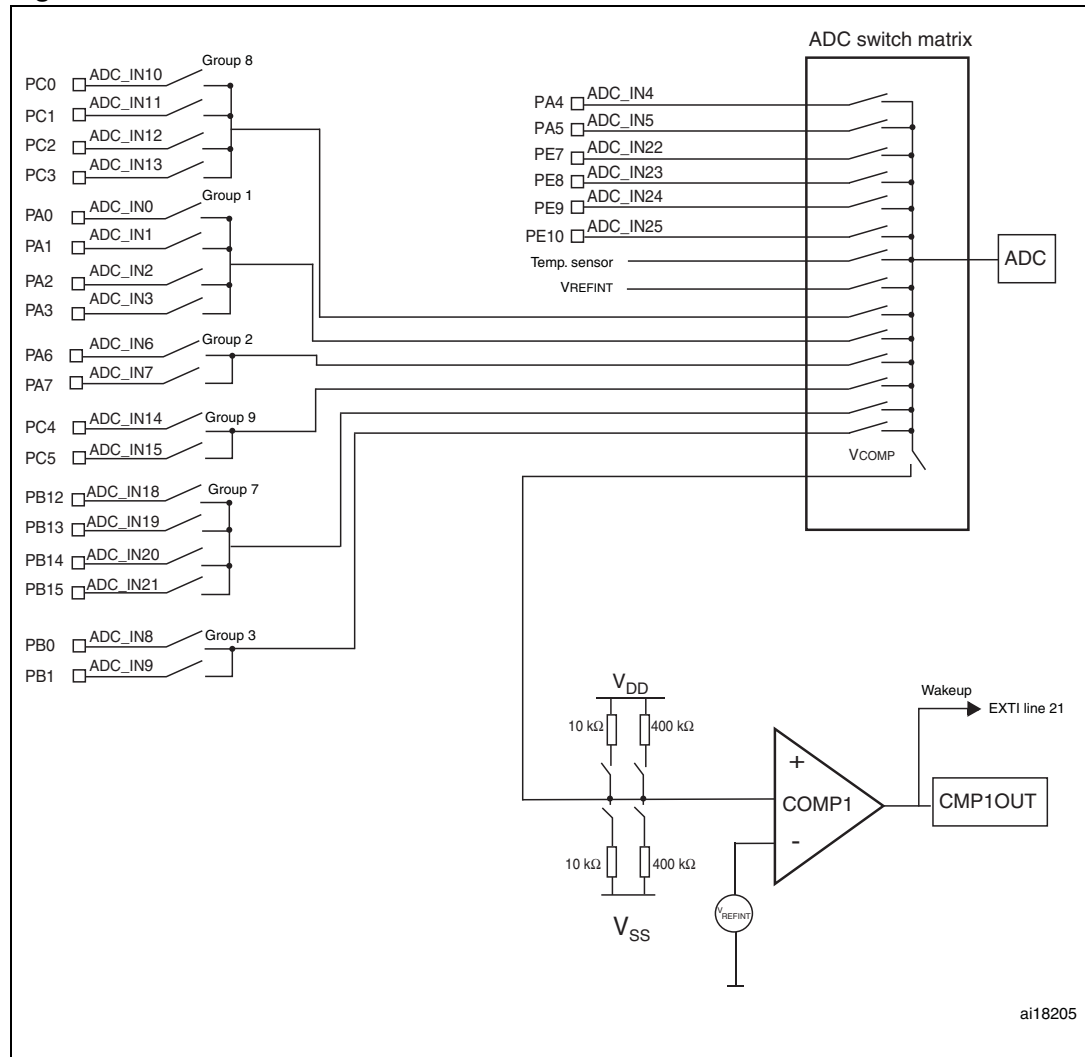

### 11.3 COMP clock

The COMP clock provided by the clock controller is synchronous with the PCLK1 (APB1 clock).

### 11.4 Comparator 1 (COMP1)

Figure 50 shows the comparator 1 interconnections.

Figure 50. COMP1 interconnections

**Note:** The internal reference voltage and temperature sensor cannot be used as COMP1 non-inverting input.  
 COMP1 comparator and ADC cannot be used at the same time since they share the ADC switch matrix.

*Note:* The internal reference voltage and temperature sensor cannot be used as COMP1 non-inverting input.

COMP1 comparator and ADC cannot be used at the same time since they share the ADC switch matrix.

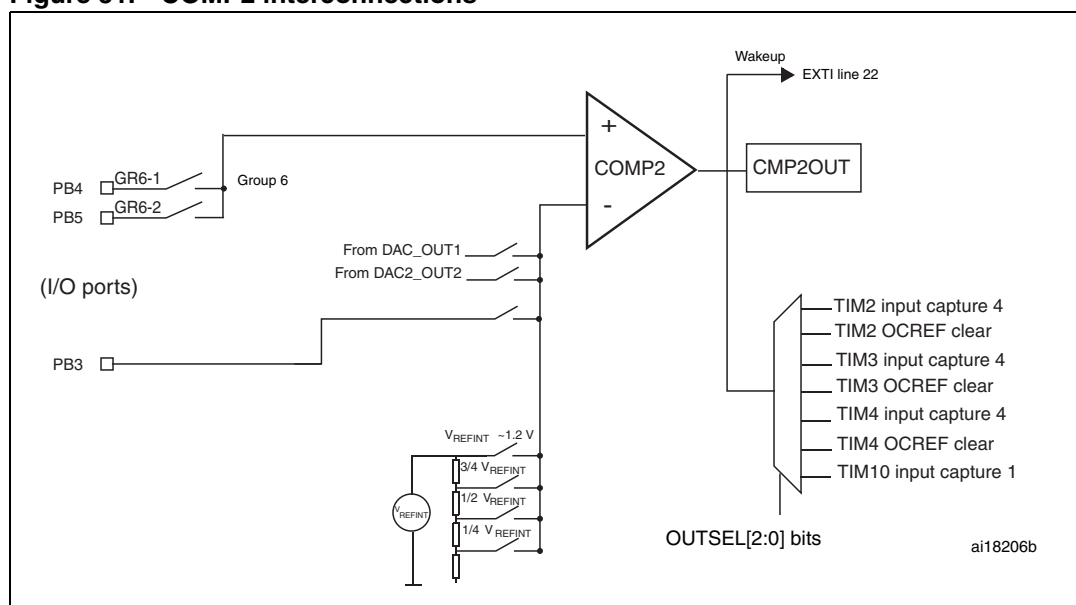

To use the COMP1 comparator, the application has to perform the following steps:

1. Enable the comparator 1 by setting the CMP1EN bit in the COMP\_CSR register
2. Wait until the comparator is ready (when the startup time has elapsed). Refer to the electrical characteristics of the STM32L15xxx datasheet.
3. Set the SCM bit in the RI\_ASCR1 register so as to close the ADC switches if the corresponding I/O switch is also closed
4. Close the ADC switches to create the path from the selected I/O to the non-inverting input. The input can be any of the up to 29 available I/Os and can be split into groups or not (see [Figure 22: I/O groups and selection on page 128](#)):
  - a) Close the VCOMP ADC analog switch by setting the VCOMP bit in the RI\_ASCR1 register.
  - b) Close the I/O analog switch number n corresponding to the I/O group that must be connected to the COMP1 non-inverting input, by setting the CHn bit in RI\_ASCR1.
5. If required enable the COMP1 interrupt by configuring and enabling EXTI line21 in interrupt mode and selecting the desired trigger event (rising edge, falling edge or both).

## 11.5 Comparator 2 (COMP2)

Figure 51 shows the comparator 2 interconnections.

**Figure 51. COMP2 interconnections**

To use the COMP2 comparator, the application has to perform the following steps:

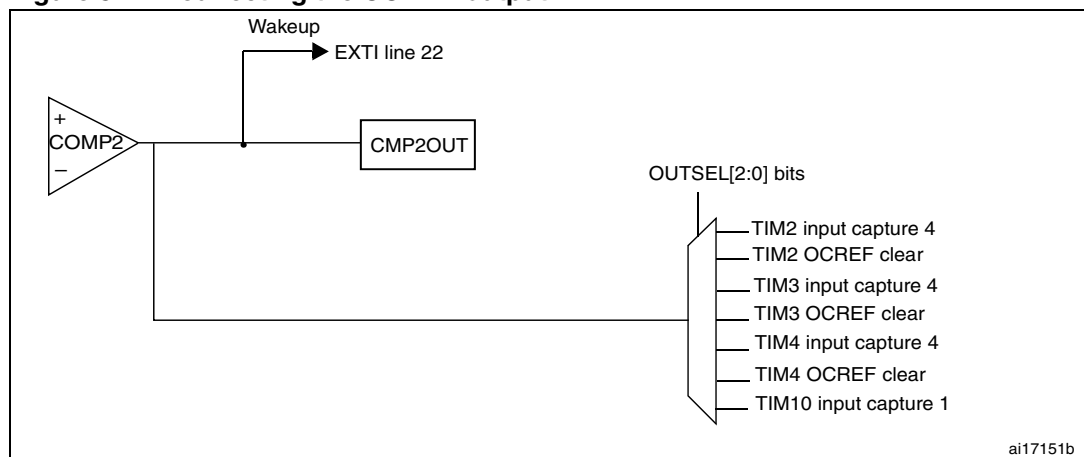

1. Select COMP2's inverting input with the INSEL[2:0] bits in COMP\_CSR.
  - In the case of an external I/O selection (PB3 I/O), the I/O should be configured in analog input mode.
2. Close the I/O's analog switch to connect to COMP2 non-inverting input. The input can be any I/O in group 6 (see [Table 22: I/O groups and selection on page 128](#)). GR6-1 or GR6-2 switches are closed as soon as the corresponding I/O is configured in analog mode.
3. Wait until the comparator is ready (when the startup time has elapsed). Refer to the electrical characteristics of the STM32L15xxx datasheet.
4. If required, perform the following procedures:
  - Select the speed with the SPEED bit in COMP\_CSR.
  - Redirect the COMP2 output to TIM2, TIM3, TIM4 or TIM10 by configuring the OUTSEL[2:0] bits in COMP\_CSR (refer to [Figure 52](#)).
  - Enable the COMP2 interrupt by configuring and enabling EXTI line22 in interrupt mode and selecting the desired sensitivity level.

*Note:* GR6-1 and GR6-2 I/O switches can be closed by either configuring the corresponding I/O (PB4 or PB5) in analog mode (Schmitt trigger disabled) or configuring the I/O in input floating mode and setting GR6-1 or GR6-2 in RI\_ASCR2 (Schmitt trigger enabled). If PB4 or PB5 is used as comparator input, it is recommended to use analog configuration to avoid any overconsumption around  $V_{DD}/2$ .

*Note:* The COMP2 comparator is enabled as soon as the inverting input is selected. The channel can be changed when the comparator is enabled.

The following figure shows the output redirection possibilities of the COMP2 output.

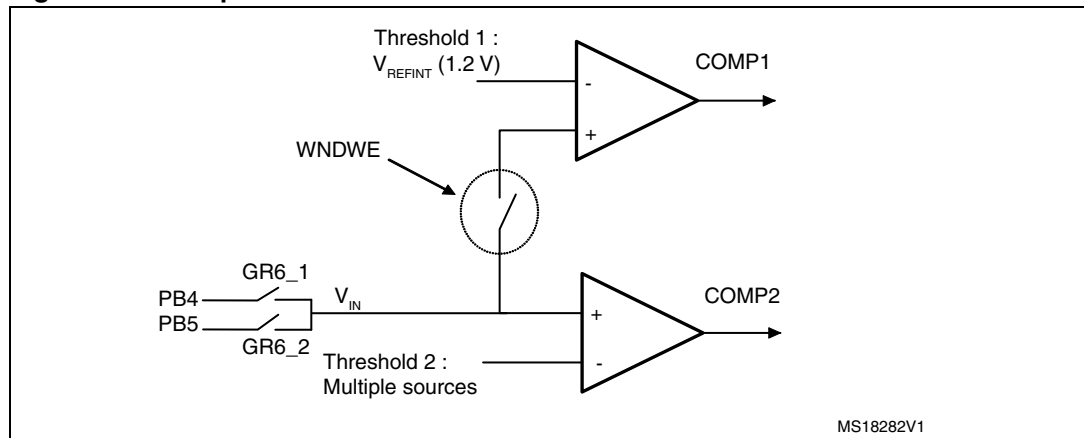

**Figure 52. Redirecting the COMP2 output**

*Note:* For more details about “clearing TIMx OCREF”, refer to [Section 13.3.11: Clearing the OCxREF signal on an external event on page 294](#).

## 11.6 Comparators in Window mode

Figure 53. Comparators in Window mode

To use the COMP1 and COMP2 comparators in window mode, the application has to perform the following steps:

1. Select COMP2's inverting input as explained in [Section 11.5: Comparator 2 \(COMP2\)](#).
2. Enable the Window mode by setting WNDWE in the COMP\_CSR register.
3. Select the non-inverting input:
  - for COMP1: follow the steps 2 and 3 from [Section 11.4: Comparator 1 \(COMP1\)](#)
  - for COMP2: follow steps 3 and 4 from [Section 11.5: Comparator 2 \(COMP2\)](#)
4. Enable COMP1 by setting the CMP1EN in the COMP\_CSR register.

*Note:* In window mode, only the Group 6 (PB4 and PB5) can be used as a non-inverting input.

## 11.7 Low power modes

Table 46. Comparator behavior in the low power modes

Mode	Description
Sleep	No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.
Stop	No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.

*Note:* Comparators cannot be used to exit the device from Sleep or Stop mode when the internal reference voltage is switched off using the ULP bit in the PWR\_CR register.

## 11.8 Interrupts

The comparator interrupts are connected to EXTI controller (lines 21 and 22).

To enable the COMP interrupt, the following sequence is required:

1. Configure and enable the EXTI line 21 (COMP1) or EXTI line 22 (COMP2) in interrupt mode and select the desired trigger event (rising edge, falling edge, or both),
2. Configure and enable the COMP\_IRQ channel in the NVIC.

## 11.9 COMP registers

The peripheral registers have to be accessed by words (32-bit).

### 11.9.1 COMP comparator control and status register (COMP\_CSR)

The COMP\_CSR register is the control/status register of the comparators. It contains all the bits related to both comparators.

Address offset: 0x00

Reset value: 0x0000 0000

31								30		29		28		27		26		25		24		23		22		21		20		19		18		17		16

Bits 31:24 Reserved, must be kept cleared.

Bits 23:21 **OUTSEL**: Comparator 2 output selection

These bits are written by software to connect the output of COMP2 to a selected timer input.

000 = TIM2 Input Capture 4

001 = TIM2 OCREF\_CLR

010 = TIM3 Input Capture 4

011 = TIM3 OCREF\_CLR

100 = TIM4 Input Capture 4

101 = TIM4 OCREF\_CLR

110 = TIM10 Input Capture 1

111 = no redirection

- Bits 20:18 **INSEL**: Inverted input selection
- 000 = no selection
  - 001 = External I/O: PB3 (COMP2\_INM)
  - 010 =  $V_{REFINT}$
  - 011 =  $3/4 V_{REFINT}$
  - 100 =  $1/2 V_{REFINT}$
  - 101 =  $1/4 V_{REFINT}$
  - 110 = DAC\_OUT1
  - 111 = DAC\_OUT2

*Note: The COMP2 comparator is enabled when the INSEL bit values are different from "000".*

- Bit 17 **WNDWE**: Window mode enable
- 0: Disabled
  - 1: Enabled

- Bit 16 **VREFOUTEN**:  $V_{REFINT}$  output enable
- This bit is used to output  $V_{REFINT}$  on Group 3 (refer to [Figure 21: Internal reference voltage output](#)).
- 0: Disabled
  - 1: Enabled

Bits 15:14 Reserved, must be kept cleared.

- Bit 13 **CMP2OUT**: Comparator 2 output
- This bit indicates the low or high level of the comparator 2 output.
- 0: Comparator 2 output is low when the non-inverting input is at a lower voltage than the inverting input
  - 1: Comparator 2 output is high when the non-inverting input is at a higher voltage than the inverting input

- Bit 12 **SPEED**: Comparator 2 speed mode
- 0: slow speed
  - 1: fast speed

Bits 11:8 Reserved, must be kept cleared.

- Bit 7 **CMP1OUT**: Comparator 1 output
- This bit indicates the high or low level of the comparator 1 output.
- 0: Comparator 1 output is low when the non-inverting input is at a lower voltage than the inverting input
  - 1: Comparator 1 output is high when the non-inverting input is at a higher voltage than the inverting input

Bits 6:5 Reserved, must be kept cleared.

- Bit 4 **CMP1EN**: Comparator 1 enable
- 0: Comparator 1 disabled
  - 1: Comparator 1 enabled

- Bit 3 **400KPD**: 400 k $\Omega$  pull-down resistor
- This bit enables the 400 k $\Omega$  pull-down resistor.
- 0: 400 k $\Omega$  pull-down resistor disabled
  - 1: 400 k $\Omega$  pull-down resistor enabled

- Bit 2 **10KPD**: 10 kΩ pull-down resistor  
 This bit enables the 10 kΩ pull-down resistor.  
 0: 10 kΩ pull-down resistor disabled  
 1: 10 kΩ pull-down resistor enabled
- Bit 1 **400KPU**: 400 kΩ pull-up resistor  
 This bit enables the 400 kΩ pull-up resistor.  
 0: 400 kΩ pull-up resistor disabled  
 1: 400 kΩ pull-up resistor enabled
- Bit 0 **10KPU**: 10 kΩ pull-up resistor  
 This bit enables the 10 kΩ pull-up resistor.  
 0: 10 kΩ pull-up resistor disabled  
 1: 10 kΩ pull-up resistor enabled

Note: 1 To avoid extra power consumption, only one resistor should be enabled at a time.

### 11.9.2 COMP register map

Table 47: COMP register map and reset values summarizes the COMP registers.

Table 47. COMP register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 12 LCD controller (LCD)

### 12.1 Introduction

The LCD controller is a digital controller/driver for monochrome passive liquid crystal display (LCD) with up to 8 common terminals and up to 44 segment terminals to drive 176 (44x4) or 320 (40x8) LCD picture elements (pixels). The exact number of terminals depends on the device pinout as described in the datasheet.

The LCD is made up of several segments (pixels or complete symbols) which can be turned visible or invisible. Each segment consists of a layer of liquid crystal molecules aligned between two electrodes. When a voltage greater than a threshold voltage is applied across the liquid crystal, the segment becomes visible. The segment voltage must be alternated to avoid an electrophoresis effect in the liquid crystal (which degrades the display). The waveform across a segment must then be generated so as to avoid having a direct current (DC).

### 12.2 LCD main features

- Highly flexible frame rate control.
- Supports Static, 1/2, 1/3, 1/4 and 1/8 duty.
- Supports Static, 1/2, 1/3 and 1/4 bias.
- Double buffered memory allows data in LCD\_RAM registers to be updated at any time by the application firmware without affecting the integrity of the data displayed.
  - LCD data RAM of up to 16 x 32-bit registers which contain pixel information (active/inactive)
- Software selectable LCD output voltage (contrast) from  $V_{LCDmin}$  to  $V_{LCDmax}$ .
- No need for external analog components:
  - A step-up converter is embedded to generate an internal  $V_{LCD}$  voltage higher than  $V_{DD}$
  - Software selection between external and internal  $V_{LCD}$  voltage source. In case of an external source, the internal boost circuit is disabled to reduce power consumption
  - A resistive network is embedded to generate intermediate  $V_{LCD}$  voltages
  - The structure of the resistive network is configurable by software to adapt the power consumption to match the capacitive charge required by the LCD panel.
- The contrast can be adjusted using two different methods:
  - When using the internal step-up converter, the software can adjust  $V_{LCD}$  between  $V_{LCDmin}$  and  $V_{LCDmax}$ .
  - Programmable dead time (up to 8 phase periods) between frames.
- Full support of Low power modes: the LCD controller can be displayed in Sleep, Low power run, Low power sleep and Low power STOP modes or can be fully disabled to reduce power consumption
- Built in phase inversion for reduced power consumption and EMI. (electromagnetic interference)
- Start of frame interrupt to synchronize the software when updating the LCD data RAM.

- Blink capability:
  - Up to 1, 2, 3, 4, 8 or all pixels which can be programmed to blink at a configurable frequency.
  - Software adjustable blink frequency to achieve around 0.5 Hz, 1 Hz, 2 Hz or 4 Hz.
- Used LCD segment and common pins should be configured as GPIO alternate functions and unused segment and common pins can be used for general purpose I/O or for another peripheral alternate function.

*Note:* 1 When the LCD relies on the internal step-up converter, the VLCD pin should be connected to  $V_{SS}$  with a capacitor. Its typical value is 1  $\mu\text{F}$  (see  $C_{EXT}$  value in the product datasheets for further information).

- 2 The VLCD pin should be connected to  $V_{DDA}$ :
- For devices without LCD
  - If the LCD peripheral is not used for devices with LCD.

## 12.3 Glossary

**Bias:** Number of voltage levels used when driving an LCD. It is defined as  $1/(\text{number of voltage levels used to drive an LCD display} - 1)$ .

**Boost circuit:** Contrast controller circuit

**Common:** Electrical connection terminal connected to several segments (44 segments).

**Duty ratio:** Number defined as  $1/(\text{number of common terminals on a given LCD display})$ .

**Frame:** One period of the waveform written to a segment.

**Frame rate:** Number of frames per second, that is, the number of times the LCD segments are energized per second.

**LCD:** (liquid crystal display) a passive display panel with terminals leading directly to a segment.

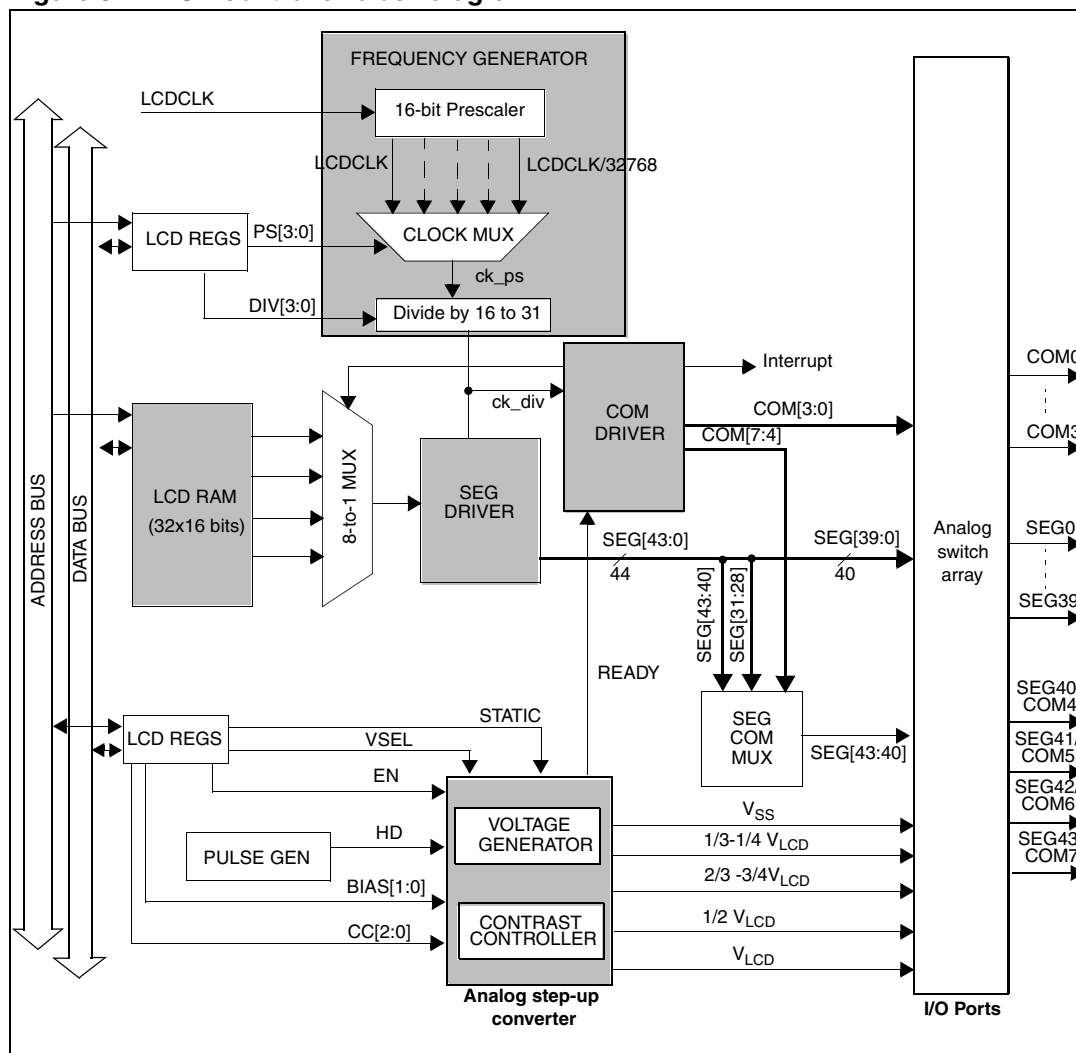

**Segment:** The smallest viewing element (a single bar or dot that is used to help create a character on an LCD display).

## 12.4 LCD functional description

### 12.4.1 General description

The LCD controller has five main blocks (see [Figure 54](#)):

**Figure 54. LCD controller block diagram**

*Note:* LCDCLK is the same as RTCCLK. Please refer to the RTC/LCD clock description in the RCC section of this manual.

### 12.4.2 Frequency generator

The frequency generator allows you to achieve various LCD frame rates starting from an LCD input clock frequency (LCDCLK) which can vary from 32 kHz up to 1 MHz.

3 different clock sources can be used to provide the LCD clock (LCDCLK/RTCCLK):

- 32 kHz Low speed external RC (LSE)
- 37 kHz Low speed internal RC (LSI)
- 1-24 MHz High speed external crystal oscillator (HSE) divided by 2, 4, 8 or 16 to obtain a 1 MHz clock

Please refer to the RTC/LCD Clock configuration in the RCC section of this manual.

This clock source must be stable in order to obtain accurate LCD timing and hence minimize DC voltage offset across LCD segments. The input clock LCDCLK can be divided by any value from 1 to  $2^{15} \times 31$  (see [Section 12.5.2: LCD frame control register \(LCD\\_FCR\) on page 263](#)). The frequency generator consists of a prescaler (16-bit ripple counter) and a 16 to 31 clock divider. The PS[3:0] bits, in the LCD\_FCR register, select LCDCLK divided by  $2^{PS[3:0]}$ . If a finer resolution rate is required, the DIV[3:0] bits, in the LCD\_FCR register, can be used to divide the clock further by 16 to 31. In this way you can roughly scale the frequency, and then fine-tune it by linearly scaling the clock with the counter. The output of the frequency generator block is  $f_{ck\_div}$  which constitutes the time base for the entire LCD controller. The  $ck\_div$  frequency is equivalent to the LCD phase frequency, rather than the frame frequency (they are equal only in case of static duty). The frame frequency ( $f_{frame}$ ) is obtained from  $f_{ck\_div}$  by dividing it by the number of active common terminals (or by multiplying it for the duty). Thus the relation between the input clock frequency ( $f_{LCDCLK}$ ) of the frequency generator and its output clock frequency  $f_{ck\_div}$  is:

$$f_{ckdiv} = \frac{f_{LCDCLK}}{2^{PS} \times (16 + DIV)}$$

$$f_{frame} = f_{ckdiv} \times duty$$

This makes the frequency generator very flexible. An example of frame rate calculation is shown in [Table 48](#).

**Table 48. Example of frame rate calculation**

LCDCLK	PS[3:0]	DIV[3:0]	Ratio	Duty	$f_{frame}$
32.768 kHz	3	1	136	1/8	30.12 Hz
32.768 kHz	4	1	272	1/4	30.12 Hz
32.768 kHz	4	6	352	1/3	31.03 Hz
32.768 kHz	5	1	544	1/2	30.12 Hz
32.768 kHz	6	1	1088	static	30.12 Hz
32.768 kHz	1	4	40	1/8	102.40 Hz
32.768 kHz	2	4	80	1/4	102.40 Hz
32.768 kHz	2	11	108	1/3	101.14 Hz

**Table 48. Example of frame rate calculation (continued)**

LCDCLK	PS[3:0]	DIV[3:0]	Ratio	Duty	f <sub>frame</sub>
32.768 kHz	3	4	160	1/2	102.40 Hz
32.768 kHz	4	4	320	static	102.40 Hz
1.00 MHz	6	3	1216	1/8	102.80 Hz
1.00 MHz	7	3	2432	1/4	102.80 Hz
1.00 MHz	7	10	3328	1/3	100.16 Hz
1.00 MHz	8	3	4864	1/2	102.80 Hz
1.00 MHz	9	3	9728	static	102.80 Hz

The frame frequency must be selected to be within a range of around ~30 Hz to ~100 Hz and is a compromise between power consumption and the acceptable refresh rate. In addition, a dedicated blink prescaler selects the blink frequency. This frequency is defined as:

$$f_{\text{BLINK}} = f_{\text{ck\_div}} / 2^{(\text{BLINKF} + 3)},$$

with BLINKF[2:0] = 0, 1, 2, ..., 7

The blink frequency achieved is in the range of 0.5 Hz, 1 Hz, 2 Hz or 4 Hz.

### 12.4.3 Common driver

Common signals are generated by the common driver block (see [Figure 54](#)).

#### COM signal bias

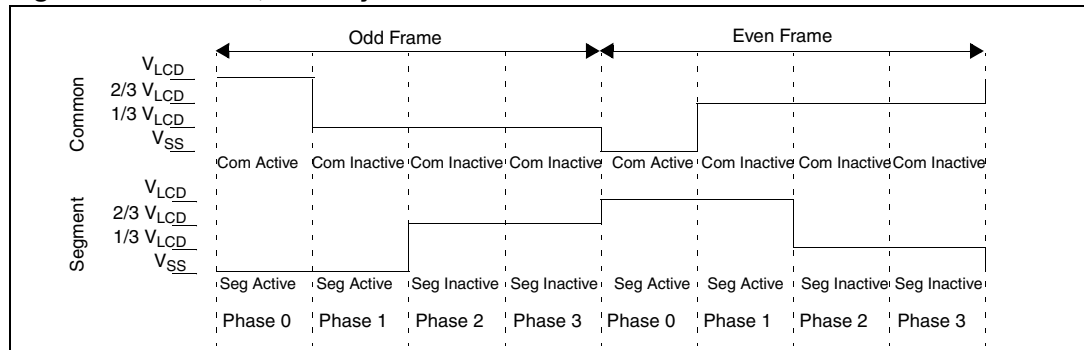

Each COM signal has identical waveforms, but different phases. It has its max amplitude  $V_{\text{LCD}}$  or  $V_{\text{SS}}$  only in the corresponding phase of a frame cycle, while during the other phases, the signal amplitude is:

- $1/4 V_{\text{LCD}}$  or  $3/4 V_{\text{LCD}}$  in case of 1/4 bias
- $1/3 V_{\text{LCD}}$  or  $2/3 V_{\text{LCD}}$  in case of 1/3 bias
- and  $1/2 V_{\text{LCD}}$  in case of 1/2 bias.

Selection between 1/2, 1/3 and 1/4 bias mode can be done through the BIAS bits in the LCD\_CR register.

A pixel is activated when both of its corresponding common and segment lines have max amplitudes during the same phase. Common signals are phase inverted in order to reduce EMI. As shown in [Figure 55](#), with phase inversion, there is a mean voltage of  $1/2 V_{\text{LCD}}$  at the end of every odd cycle.

**Figure 55. 1/3 bias, 1/4 duty**

In case of 1/2 bias (BIAS = 01) the  $V_{LCD}$  pin generates an intermediate voltage (node B = node A) equal to  $1/2 V_{LCD}$  for odd and even frames (see [Figure 62](#)).

**COM signal duty**

Depending on the DUTY[2:0] bits in the LCD\_CR register, the COM signals are generated with static duty (see [Figure 57](#)), 1/2 duty (see [Figure 58](#)), 1/3 duty (see [Figure 59](#)), 1/4 duty (see [Figure 60](#)) or 1/8 duty (see [Figure 61](#)).

COM[n] n[0 to 7] is active during phase n in the odd frame, so the COM pin is driven to  $V_{LCD}$ . During phase n of the even frame the COM pin is driven to  $V_{SS}$ .

In the case of 1/3 or 1/4) bias:

- COM[n] is inactive during phases other than n so the COM pin is driven to  $1/3 (1/4) V_{LCD}$  during odd frames and to  $2/3 (3/4) V_{LCD}$  during even frames

In the case of 1/2 bias:

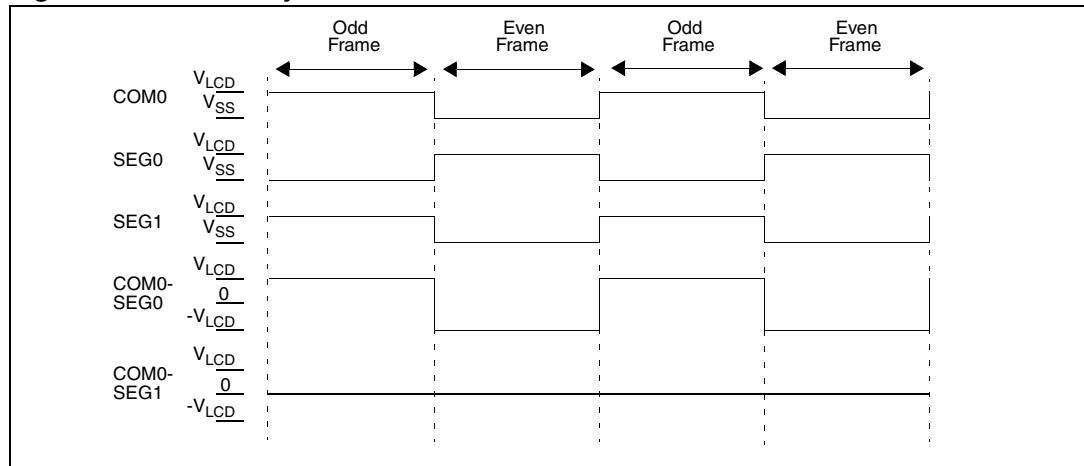

- If COM[n] is inactive during phases other than n, the COM pin is always driven (odd and even frame) to  $1/2 V_{LCD}$ .

When static duty is selected, the segment lines are not multiplexed, which means that each segment output corresponds to one pixel. In this way only up to 44 pixels can be driven. COM[0] is always active while COM[7:1] are not used and are driven to  $V_{SS}$ .

When the LCDEN bit in the LCD\_CR register is reset, all common lines are pulled down to  $V_{SS}$  and the ENS flag in the LCD\_SR register becomes 0. Static duty means that COM[0] is always active and only two voltage levels are used for the segment and common lines:  $V_{LCD}$  and  $V_{SS}$ . A pixel is active if the corresponding SEG line has a voltage opposite to that of the COM, and inactive when the voltages are equal. In this way the LCD has maximum contrast (see [Figure 56](#), [Figure 57](#)). In the [Figure 56](#) pixel 0 is active while pixel 1 is inactive.

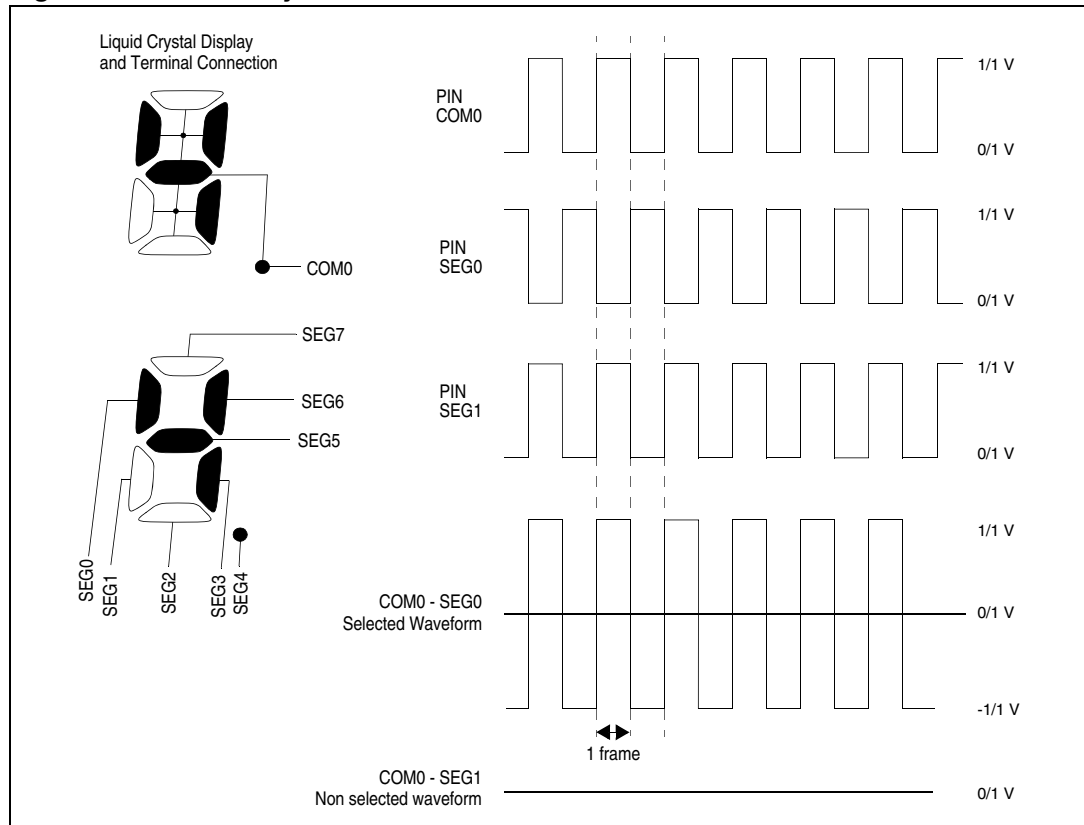

Figure 56. Static duty

In each frame there is only one phase, this is why  $f_{frame}$  is equal to  $f_{LCD}$ . If 1/4 duty is selected there are four phases in a frame in which COM[0] is active during phase 0, COM[1] is active during phase 1, COM[2] is active during phase 2, and COM[3] is active during phase 3.

Figure 57. Static duty

In this mode, the segment terminals are multiplexed and each of them control four pixels. A pixel is activated only when both of its corresponding SEG and COM lines are active in the same phase. In case of 1/4 duty, to deactivate pixel 0 connected to COM[0] the SEG[0] needs to be inactive during the phase 0 when COM[0] is active. To activate pixel44

connected to COM[1] the SEG[0] needs to be active during phase 1 when COM[1] is active (see [Figure 60](#)). To activate pixels from 0 to 43 connected to COM[0], SEG[0:43] need to be active during phase 0 when COM[0] is active. These considerations can be extended to the other pixels.

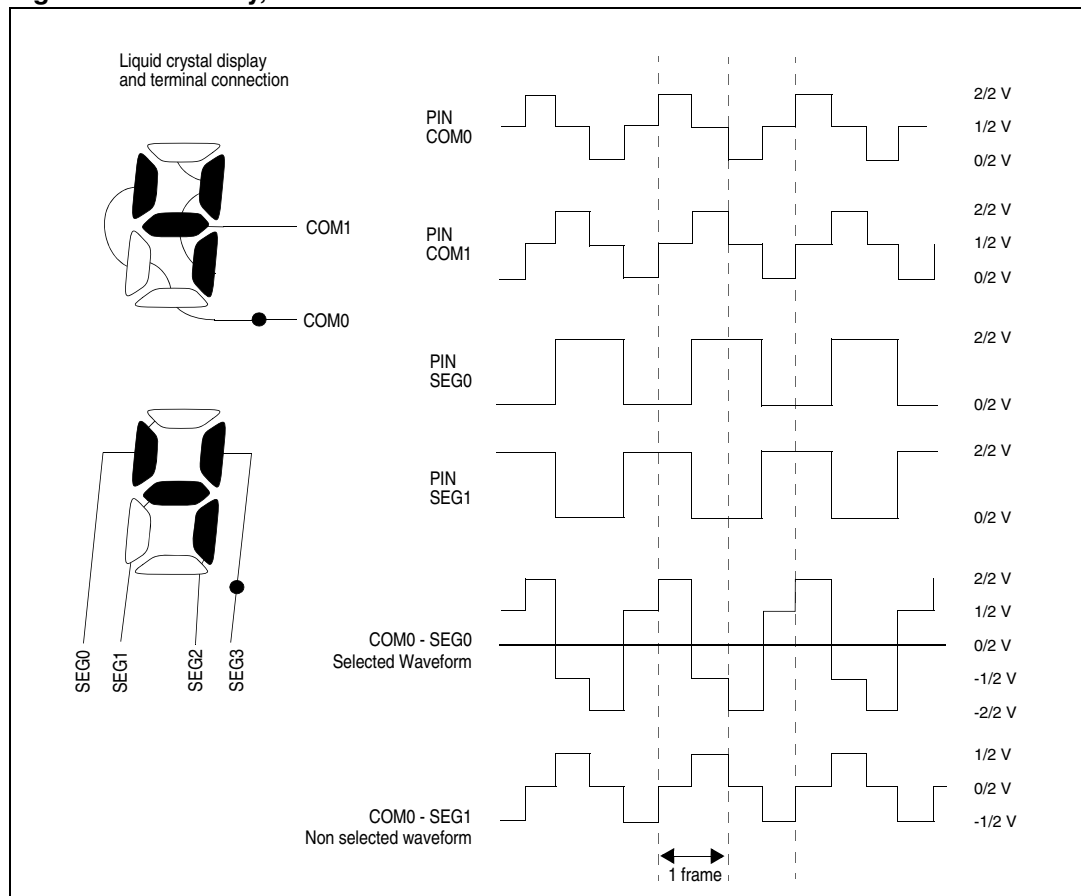

### 8 to 1 Mux

When COM[0] is active the common driver block, also drives the 8 to 1 mux shown in [Figure 54](#) in order to select the content of first two RAM register locations. When COM[7] is active, the output of the 8 to 1 mux is the content of the last two RAM locations.

### Start of frame (SOF)

The common driver block is also able to generate an SOF (start of frame flag) (see [Section 12.5.3: LCD status register \(LCD\\_SR\)](#)). The LCD start of frame interrupt is executed if the SOFIE (start of frame interrupt enable) bit is set (see [Section 12.5.2: LCD frame control register \(LCD\\_FCR\)](#)). SOF is cleared by writing the SOFC bit to 1 in the LCD\_CLR register when executing the corresponding interrupt handling vector.

**Figure 58. 1/2 duty, 1/2 bias**

#### 12.4.4 Segment driver

The segment driver block controls the SEG lines according to the pixel data coming from the 8 to 1 mux driven in each phase by the common driver block.

##### In the case of 1/4 or 1/8 duty

When COM[0] is active, the pixel information (active/inactive) related to the pixel connected to COM[0] (content of the first two LCD\_RAM locations) goes through the 8 to 1 mux.

The SEG[ $n$ ] pin  $n$  [0 to 43] is driven to  $V_{SS}$  (indicating pixel  $n$  is active when COM[0] is active) in phase 0 of the odd frame,

The SEG[ $n$ ] pin is driven to  $V_{LCD}$  in phase 0 of the even frame. If pixel  $n$  is inactive then the SEG[ $n$ ] pin is driven to  $2/3$  ( $2/4$ )  $V_{LCD}$  in the odd frame or  $1/3$  ( $2/4$ )  $V_{LCD}$  in the even frame (current inversion in  $V_{LCD}$  pad). (see [Figure 55](#))

In case of 1/2 bias, if the pixel is inactive the SEG[ $n$ ] pin is driven to  $V_{LCD}$  in the odd and to  $V_{SS}$  in the even frame.

When the LCD controller is disabled (LCDEN bit cleared in the LCD\_CR register) then the SEG lines are pulled down to  $V_{SS}$ .

Figure 59. 1/3 duty, 1/3 bias

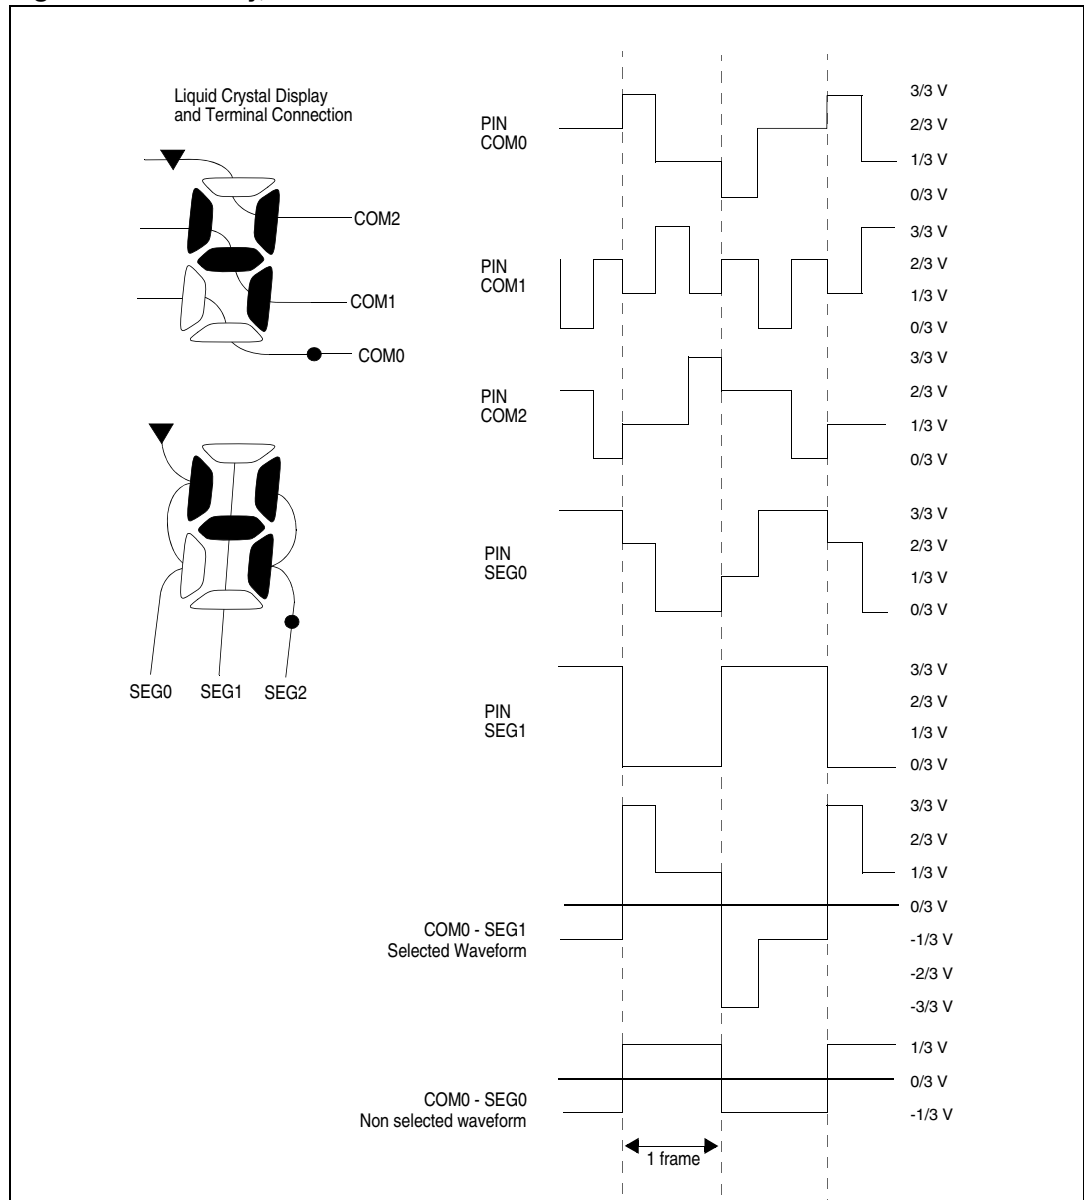

Figure 60. 1/4 duty, 1/3 bias

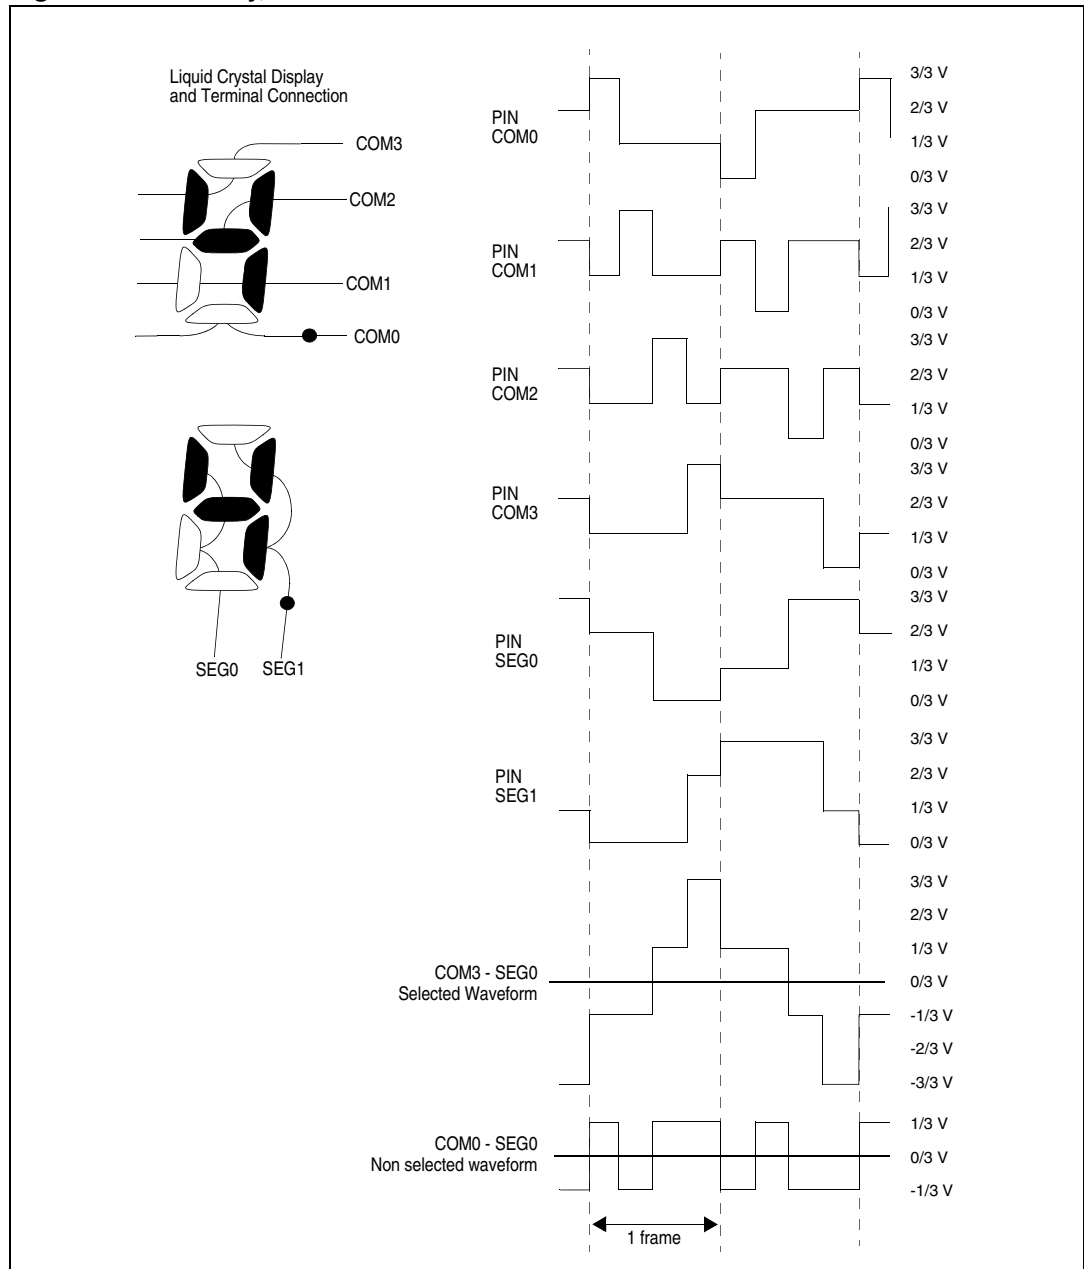

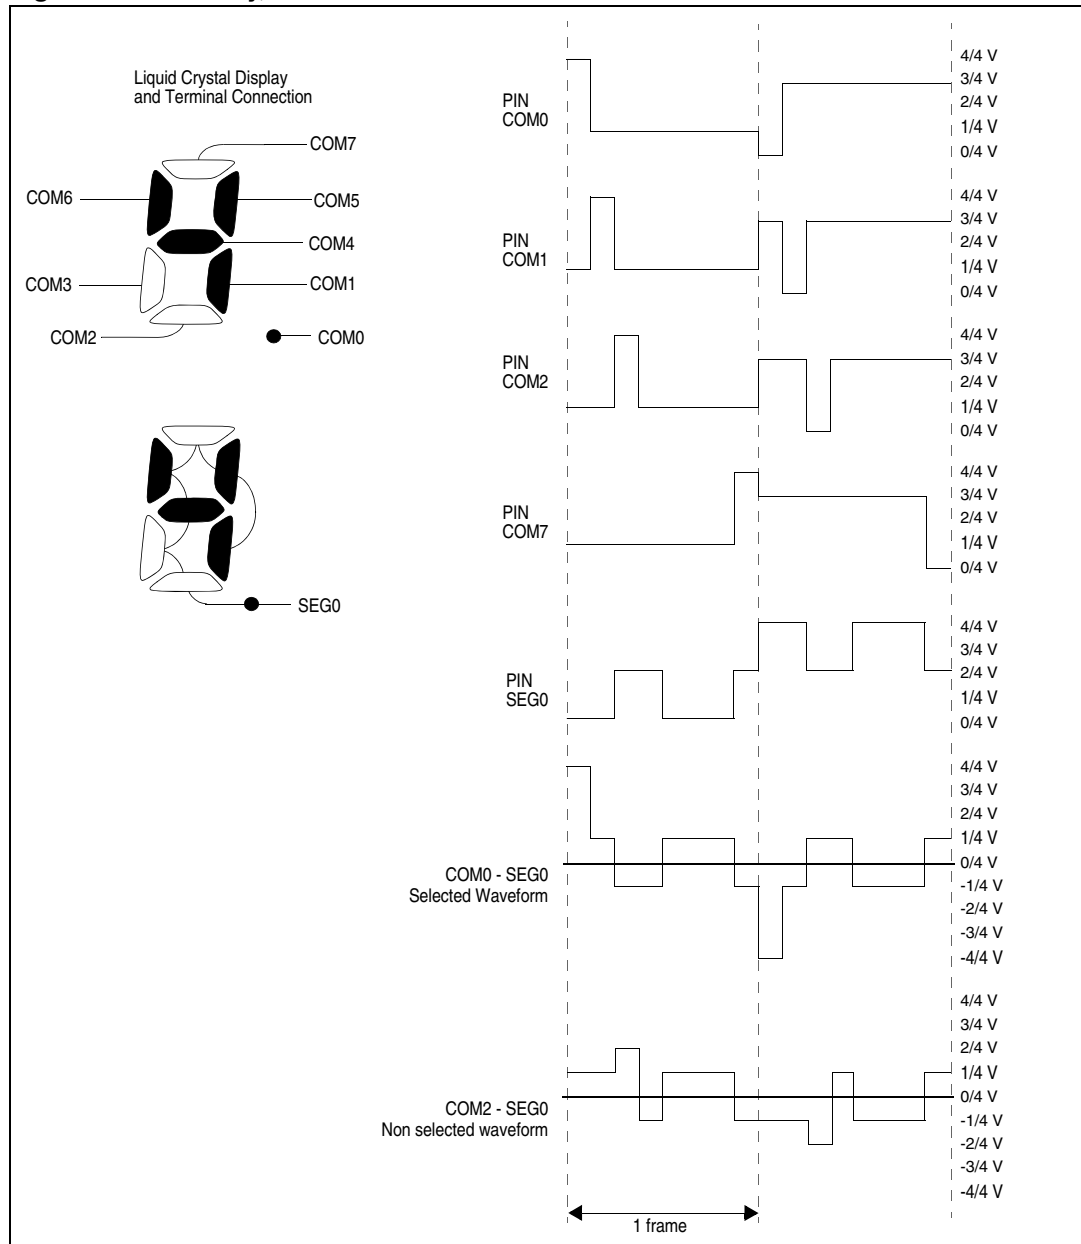

Figure 61. 1/8 duty, 1/4 bias

## Blink

The segment driver also implements a programmable blink feature to allow some pixels to continuously switch on at a specific frequency. The blink mode can be configured by the BLINK[1:0] bits in the LCD\_FCR register, making possible to blink up to 1, 2, 4, 8 or all pixels (see [Section 12.5.2: LCD frame control register \(LCD\\_FCR\)](#)). The blink frequency can be selected from eight different values using the BLINKF[2:0] bits in the LCD\_FCR register.

[Table 49](#) gives examples of different blink frequencies (as a function of ck\_div frequency).

**Table 49. Blink frequency**

BLINKF[2:0] bits			ck_div frequency (with LCDCLK frequency of 32.768 kHz)			
			32 Hz	64 Hz	128 Hz	256 Hz
0	0	0	4.0 Hz	N/A	N/A	N/A
0	0	1	2.0 Hz	4.0 Hz	N/A	N/A
0	1	0	<b>1.0 Hz</b>	2.0 Hz	4.0 Hz	N/A
0	1	1	0.5 Hz	<b>1.0 Hz</b>	2.0 Hz	4.0 Hz
1	0	0	0.25 Hz	0.5 Hz	<b>1.0 Hz</b>	2.0 Hz
1	0	1	N/A	0.25 Hz	0.5 Hz	<b>1.0 Hz</b>
1	1	0	N/A	N/A	0.25 Hz	0.5 Hz
1	1	1	N/A	N/A	N/A	0.25 Hz

## 12.4.5 Voltage generator

The LCD voltage levels are generated by the  $V_{LCD}$  pin or by the internal voltage step-up converter (depending on the VSEL bit in the LCD\_CR register), through an internal resistor divider network as shown in [Figure 62](#).

The LCD voltage generator generates up to three intermediate voltage levels ( $1/3 V_{LCD}$ ,  $2/3 V_{LCD}$  or  $1/4 V_{LCD}$ ,  $2/4 V_{LCD}$ ,  $3/4 V_{LCD}$ ) between  $V_{SS}$  and  $V_{LCD}$  in case of  $1/3$  ( $1/4$ ) bias and only one voltage level ( $1/2 V_{LCD}$ ) between  $V_{SS}$  and  $V_{LCD}$  in case of  $1/2$  bias.

In the case of  $1/3$  or  $1/4$  bias:

- **During odd frames**, node b voltage ( $V_{bCOM}$ ) is  $1/3$  ( $1/4$ )  $V_{LCD}$ , while node a voltage ( $V_{aSEG}$ ) is  $2/3$  ( $3/4$ )  $V_{LCD}$ ,
- **During even frames**, node b voltage is  $2/3$  ( $3/4$ )  $V_{LCD}$  and node a voltage is  $1/3$  ( $1/4$ )  $V_{LCD}$ .

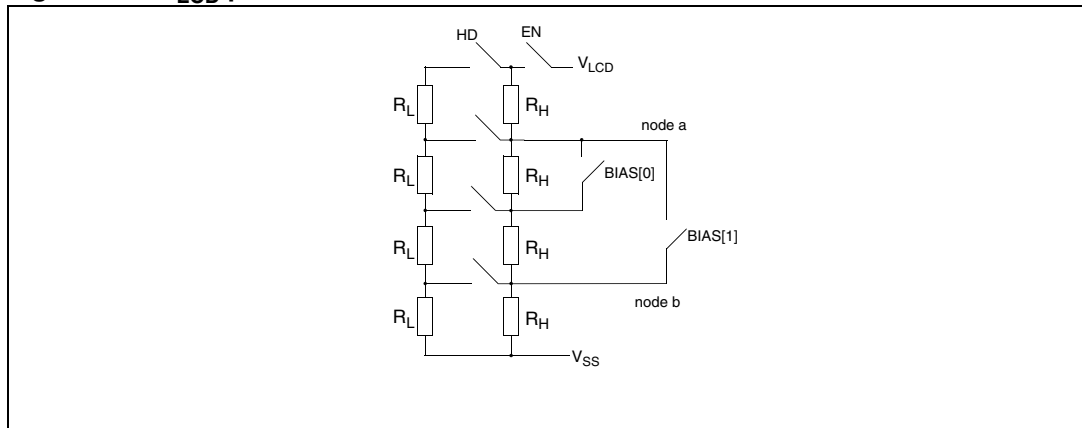

In the case of  $1/2$  bias:

- Node a voltage is equal to node b voltage and its value is  $1/2 V_{LCD}$ .

For the divider network, two resistive networks one with low value resistors ( $R_L$ ) and one with high value resistors ( $R_H$ ) are respectively used to increase the current during transitions and to reduce power consumption in static state.

The PON[2:0] (Pulse ON duration) bits in the LCD\_FCR register configure the time during which  $R_L$  is enabled (see [Figure 54](#)) when the levels of the common and segment lines change. A short drive time will lead to lower power consumption, but displays with high internal resistance may need a longer drive time to achieve satisfactory contrast.

Figure 62.  $V_{LCD}$  pin for 1/2 1/3 1/4 bias

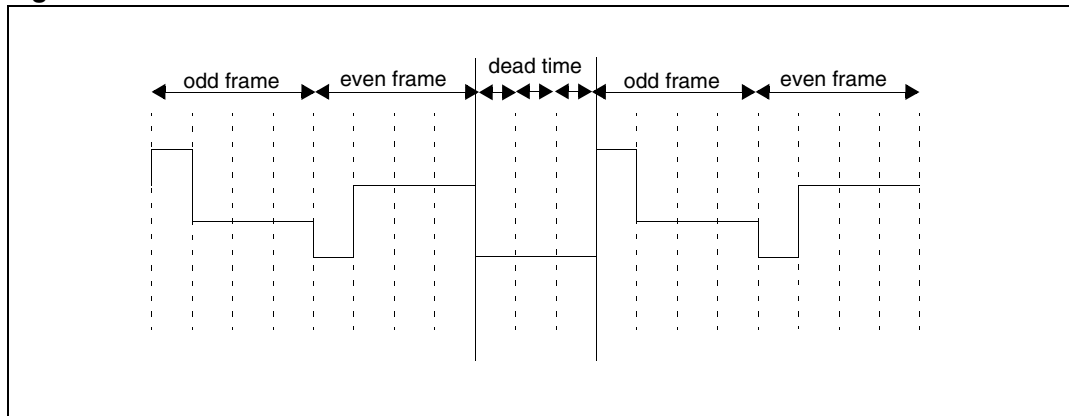

The  $R_L$  divider can be always switched on using the HD bit in the LCD\_FCR configuration register (see [Section 12.5.2](#)). The  $V_{LCD}$  value can be chosen among a wide set of values from  $V_{LCDmin}$  to  $V_{LCDmax}$  by means of CC[2:0] (Contrast Control) bits inside LCD\_FCR (see [Section 12.5.2](#)) register. New values of  $V_{LCD}$  takes effect every beginning of a new frame.

After the LCDEN bit is activated the voltage generator sets the RDY bit in the LCD\_SR register to indicate that the voltage levels are stable and the LCD controller can start to work.

**Deadtime**

In addition to using the CC[2:0] bits, the contrast can be controlled by programming a dead time between each frame. During the dead time the COM and SEG values are put to  $V_{SS}$ . The DEAD[2:0] bits in the LCD\_FCR register can be used to program a time of up to eight phase periods. This dead time reduces the contrast without modifying the frame rate.

Figure 63. Deadtime

### 12.4.6 Double buffer memory

Using its double buffer memory the LCD controller ensures the coherency of the displayed information without having to use interrupts to control LCD\_RAM modification.

The application software can access the first buffer level (LCD\_RAM) through the APB interface. Once it has modified the LCD\_RAM, it sets the UDR flag in the LCD\_SR register. This UDR flag (update display request) requests the updated information to be moved into the second buffer level (LCD\_DISPLAY).

This operation is done synchronously with the frame (at the beginning of the next frame), until the update is completed, the LCD\_RAM is write protected and the UDR flag stays high. Once the update is completed another flag (UDD - Update Display Done) is set and generates an interrupt if the UDDIE bit in the LCD\_FCR register is set.

The time it takes to update LCD\_DISPLAY is, in the worst case, one odd and one even frame.

The update will not occur (UDR = 1 and UDD = 0) until the display is enabled (LCDEN = 1)

### 12.4.7 COM and SEG multiplexing

#### Output pins versus duty modes

The output pins consists of:

- SEG[43:0]
- COM[3:0]

Depending on the duty configuration, the COM and SEG output pins may have different functions:

- In static, 1/2, 1/3 and 1/4 duty modes there are up to 44 SEG pins and respectively 1, 2, 3 and 4 COM pins
- In 1/8 duty mode (DUTY[2:0] = 100), the COM[7:4] outputs are available on the SEG[43:40] pins, reducing to the number of available segments 40.

#### Remapping capability

Additionally, it is possible to remap 4 segments by setting the MUX\_SEG bit in the LCD\_CR register. This is particularly useful when using smaller device types with fewer external pins.

When MUX\_SEG is set, output pins SEG[43:40] have function SEG[31:28].

#### Summary of COM and SEG functions versus duty and remap

All the possible ways of multiplexing the COM and SEG functions are described in [Table 50](#). [Figure 64](#) gives examples showing the signal connections to the external pins.

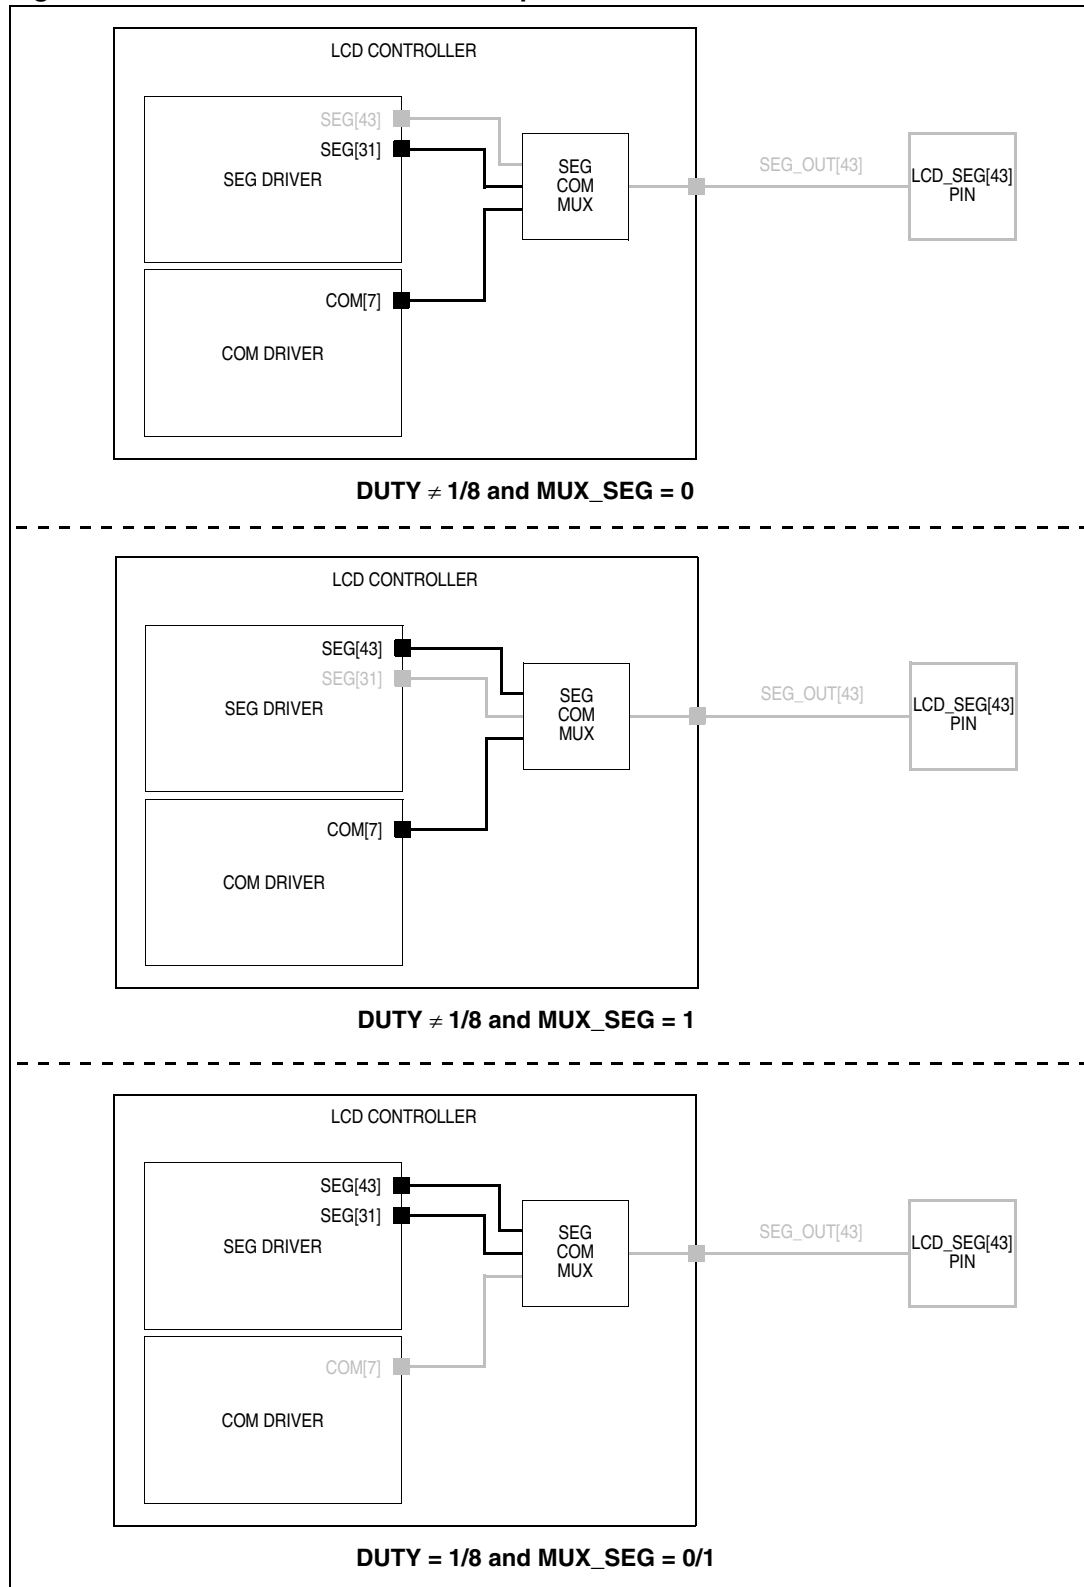

Table 50. Remapping capability

Configuration bits		Capability	Output pin	Function
DUTY	MUX_SEG			
1/8	0	40x8	SEG[43:40]	COM[7:4]
			COM[3:0]	COM[3:0]
			SEG[39:0]	SEG[39:0]
	1	28x8	SEG[43:40]	COM[7:4]
			COM[3:0]	COM[3:0]
			SEG[39:28]	not used
SEG[27:0]	SEG[27:0]			
1/4	0	44x4	COM[3:0]	COM[3:0]
			SEG[43:0]	SEG[43:0]
	1	32x4	COM[3:0]	COM[3:0]
			SEG[43:40]	SEG[31:28]
			SEG[39:28]	not used
			SEG[27:0]	SEG[27:0]
1/3	0	44x3	COM[3]	not used
			COM[2:0]	COM[2:0]
			SEG[43:0]	SEG[43:0]
	1	32x3	COM[3]	not used
			COM[2:0]	COM[2:0]
			SEG[43:40]	SEG[31:28]
SEG[39:28]			not used	
SEG[27:0]	SEG[27:0]			
1/2	0	44x2	COM[3:2]	not used
			COM[1:0]	COM[1:0]
			SEG[43:0]	SEG[43:0]
	1	32x2	COM[3:2]	not used
			COM[1:0]	COM[1:0]
			SEG[43:40]	SEG[31:28]
SEG[39:28]			not used	
SEG[27:0]	SEG[27:0]			

Table 50. Remapping capability (continued)

Configuration bits		Capability	Output pin	Function
DUTY	MUX_SEG			
STATIC	0	44x1	COM[3:1]	not used
			COM[0]	COM[0]
			SEG[43:0]	SEG[43:0]

Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								MUX_SEG	BIAS[1:0]		DUTY[2:0]			VSEL	LCDEN
								rw/r	rw/r	rw/r	rw/r	rw/r	rw/r	rw/r	rw

Bits 31:8 Reserved, must be kept cleared.

Bit 7 **MUX\_SEG**: Mux segment enable

This bit is used to enable SEG pin remapping. Four SEG pins can be multiplexed with SEG[31:28]. See [Section 12.4.7](#).

- 0: SEG pin multiplexing disabled
- 1: SEG[31:28] are multiplexed with SEG[43:40]

Bits 6:5 **BIAS[1:0]**: Bias selector

These bits determine the bias used. Value 11 is forbidden.

- 00: Bias 1/4
- 01: Bias 1/2
- 10: Bias 1/3
- 11: Reserved

Bits 4:2 **DUTY[2:0]**: Duty selection

These bits determine the duty cycle. Values 101, 110 and 111 are forbidden.

- 000: Static duty
- 001: 1/2 duty
- 010: 1/3 duty
- 011: 1/4 duty
- 100: 1/8 duty
- 101: Reserved
- 110: Reserved
- 111: Reserved

Bit 1 **VSEL**: Voltage source selection

The VSEL bit determines the voltage source for the LCD.

- 0: Internal source (voltage step-up converter)
- 1: External source ( $V_{LCD}$  pin)

Bit 0 **LCDEN**: LCD controller enable

This bit is set by software to enable the LCD Controller/Driver. It is cleared by software to turn off the LCD at the beginning of the next frame. When the LCD is disabled all COM and SEG pins are driven to  $V_{SS}$ .

- 0: LCD Controller disabled
- 1: LCD Controller enabled

Note: The VSEL, MUX\_SEG, BIAS and DUTY bits are write protected when the LCD is enabled (ENS bit in LCD\_SR to 1).

### 12.5.2 LCD frame control register (LCD\_FCR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved						PS[3:0]				DIV[3:0]				BLINK[1:0]	
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLINKF[2:0]			CC[2:0]			DEAD[2:0]			PON[2:0]			UDDIE	Res.	SOFIE	HD
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw

Bits 31:26 Reserved, must be kept cleared.

Bits 25:22 **PS[3:0]**: PS 16-bit prescaler

These bits are written by software to define the division factor of the PS 16-bit prescaler.  
 $ck\_ps = LCDCLK/(2)$ . See [Section 12.4.2](#).

- 0000:  $ck\_ps = LCDCLK$
- 0001:  $ck\_ps = LCDCLK/2$
- 0002:  $ck\_ps = LCDCLK/4$
- ...
- 1111:  $ck\_ps = LCDCLK/32768$

Bits 21:18 **DIV[3:0]**: DIV clock divider

These bits are written by software to define the division factor of the DIV divider. See [Section 12.4.2](#).

- 0000:  $ck\_div = ck\_ps/16$
- 0001:  $ck\_div = ck\_ps/17$
- 0002:  $ck\_div = ck\_ps/18$
- ...
- 1111:  $ck\_div = ck\_ps/31$

Bits 17:16 **BLINK[1:0]**: Blink mode selection

- 00: Blink disabled
- 01: Blink enabled on SEG[0], COM[0] (1 pixel)
- 10: Blink enabled on SEG[0], all COMs (up to 8 pixels depending on the programmed duty)
- 11: Blink enabled on all SEGs and all COMs (all pixels)

Bits 15:13 **BLINKF[2:0]**: Blink frequency selection

- 000:  $f_{LCD}/8$
- 001:  $f_{LCD}/16$
- 010:  $f_{LCD}/32$
- 011:  $f_{LCD}/64$
- 100:  $f_{LCD}/128$
- 101:  $f_{LCD}/256$
- 110:  $f_{LCD}/512$
- 111:  $f_{LCD}/1024$

Bits 12:10 **CC[2:0]**: Contrast control

These bits specify one of the  $V_{LCD}$  maximum voltage (independent of  $V_{DD}$ ). It ranges from 2.60 V to 3.51V.

*Note:* 000:  $V_{LCD0}$   
 001:  $V_{LCD1}$   
 010:  $V_{LCD2}$   
 011:  $V_{LCD3}$   
 100:  $V_{LCD4}$   
 101:  $V_{LCD5}$   
 110:  $V_{LCD6}$   
 111:  $V_{LCD7}$

Bits 9:7 **DEAD[2:0]**: Dead time duration

These bits are written by software to configure the length of the dead time between frames. During the dead time the COM and SEG voltage levels are held at 0 V to reduce the contrast without modifying the frame rate.

000: No dead time  
 001: 1 phase period dead time  
 010: 2 phase period dead time  
 .....  
 111: 7 phase period dead time

Bits 6:4 **PON[2:0]**: Pulse ON duration

These bits are written by software to define the pulse duration in terms of  $ck\_ps$  pulses. A short pulse will lead to lower power consumption, but displays with high internal resistance may need a longer pulse to achieve satisfactory contrast. Note that the pulse will never be longer than one half prescaled LCD clock period.

000: 0	100: 4/ $ck\_ps$
001: 1/ $ck\_ps$	101: 5/ $ck\_ps$
010: 2/ $ck\_ps$	110: 6/ $ck\_ps$
011: 3/ $ck\_ps$	111: 7/ $ck\_ps$

PON duration example with  $LCDCLK = 32.768$  kHz and  $PS=0x03$ :

000: 0 $\mu$ s	100: 976 $\mu$ s
001: 244 $\mu$ s	101: 1.22 ms
010: 488 $\mu$ s	110: 1.46 ms
011: 782 $\mu$ s	111: 1.71 ms

Bit 3 **UDDIE**: Update display done interrupt enable

This bit is set and cleared by software.

0: LCD Update Display Done interrupt disabled  
 1: LCD Update Display Done interrupt enabled

Bit 2 Reserved, must be kept cleared.

Bit 1 **SOFIE**: Start of frame interrupt enable

This bit is set and cleared by software.

0: LCD Start of Frame interrupt disabled

1: LCD Start of Frame interrupt enabled

Bit 0 **HD**: High drive enable

This bit is written by software to enable a low resistance divider. Displays with high internal resistance may need a longer drive time to achieve satisfactory contrast. This bit is useful in this case if some additional power consumption can be tolerated.

0: Permanent high drive disabled

1: Permanent high drive enabled. When HD=1, then the PON bits have to be programmed to 001.

*Note: The data in this register can be updated any time, however the new values are applied only at the beginning of the next frame (except for CC, UDDIE, SOFIE that affect the device behavior immediately).*

*Reading this register obtains the last value written in the register and not the configuration used to display the current frame.*

### 12.5.3 LCD status register (LCD\_SR)

Address offset: 0x08

Reset value: 0x0000 0020

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										FCRSF	RDY	UDD	UDR	SOF	ENS
										r	r	r	rs	r	r

Bits 31:6 Reserved, must be kept cleared.

Bit 5 **FCRSF**: LCD Frame Control Register Synchronization flag

This bit is set by hardware each time the LCD\_FCR register is updated in the LCDCLK domain. It is cleared by hardware when writing to the LCD\_FCR register.

0: LCD Frame Control Register not yet synchronized

1: LCD Frame Control Register synchronized

Bit 4 **RDY**: Ready flag

This bit is set and cleared by hardware. It indicates the status of the step-up converter.

0: Not ready

1: Step-up converter is enabled and ready to provide the correct voltage.

**Bit 3 UDD:** Update Display Done

This bit is set by hardware. It is cleared by writing 1 to the UDDC bit in the LCD\_CLR register. The bit set has priority over the clear.

0: No event

1: Update Display Request done. A UDD interrupt is generated if the UDDIE bit in the LCD\_FCR register is set.

*Note: If the device is in STOP mode (PCLK not provided) UDD will not generate an interrupt even if UDDIE = 1.*

*If the display is not enabled the UDD interrupt will never occur.*

**Bit 2 UDR:** Update display request

Each time software modifies the LCD\_RAM it must set the UDR bit to transfer the updated data to the second level buffer. The UDR bit stays set until the end of the update and during this time the LCD\_RAM is write protected.

0: No effect

1: Update Display request

*Note: When the display is disabled, the update is performed for all LCD\_DISPLAY locations. When the display is enabled, the update is performed only for locations for which commons are active (depending on DUTY). For example if DUTY = 1/2, only the LCD\_DISPLAY of COM0 and COM1 will be updated.*

*Note: Writing 0 on this bit or writing 1 when it is already 1 has no effect. This bit can be cleared by hardware only. It can be cleared only when LCDEN = 1*

**Bit 1 SOF:** Start of frame flag

This bit is set by hardware at the beginning of a new frame, at the same time as the display data is updated. It is cleared by writing a 1 to the SOFC bit in the LCD\_CLR register. The bit clear has priority over the set.

0: No event

1: Start of Frame event occurred. An LCD Start of Frame Interrupt is generated if the SOFIE bit is set.

**Bit 0 ENS:** LCD enabled status

This bit is set and cleared by hardware. It indicates the LCD controller status.

0: LCD Controller disabled.

1: LCD Controller enabled

*Note: The ENS bit is set immediately when the LCDEN bit in the LCD\_CR goes from 0 to 1. On deactivation it reflects the real status of LCD so it becomes 0 at the end of the last displayed frame.*

### 12.5.4 LCD clear register (LCD\_CLR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## 13 General-purpose timers (TIM2 to TIM4)

### 13.1 TIM2 to TIM4 introduction

The general-purpose timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (*input capture*) or generating output waveforms (*output compare and PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

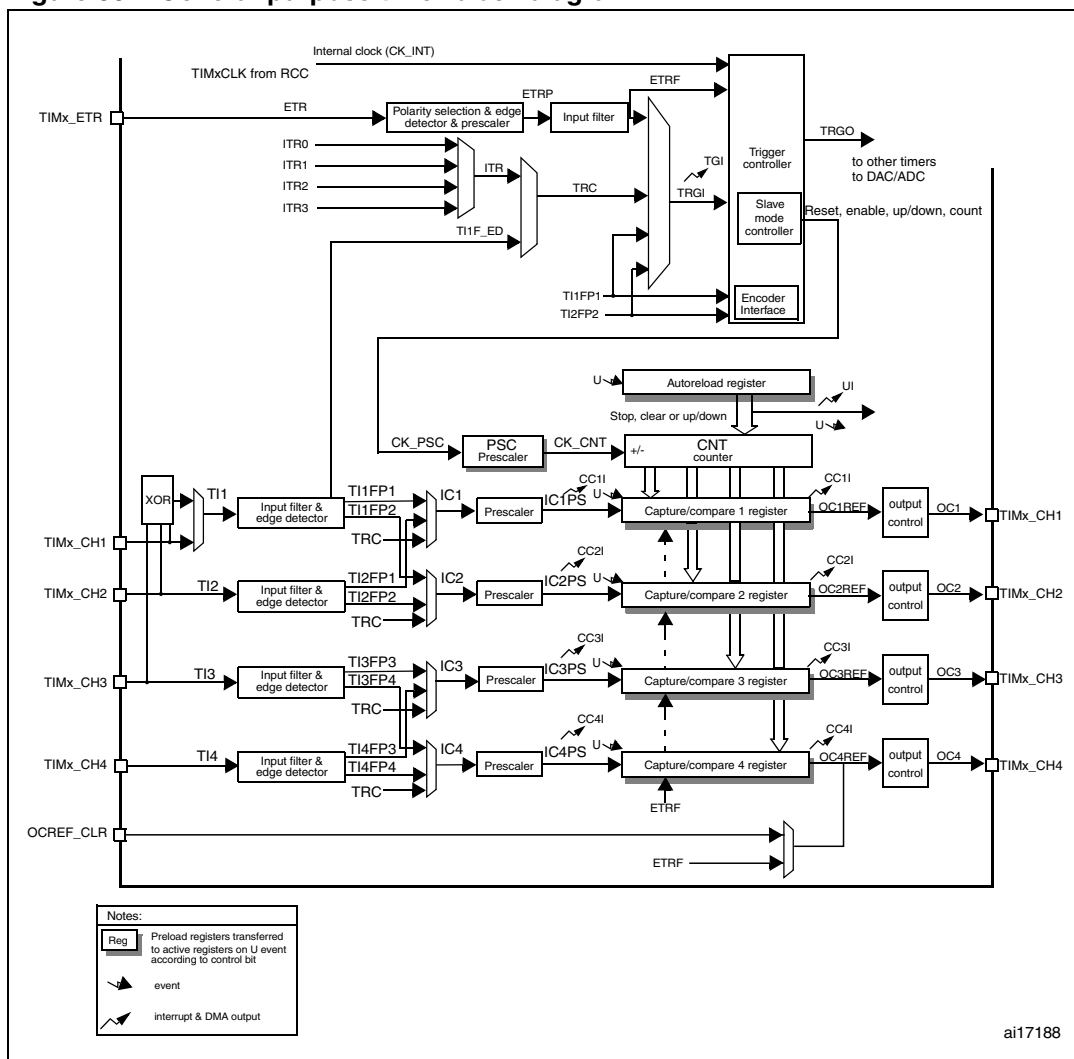

The timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 13.3.15](#).

### 13.2 TIM2 to TIM4 main features

General-purpose TIMx timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

Figure 66. General-purpose timer block diagram

## 13.3 TIM2 to TIM4 functional description

### 13.3.1 Time-base unit

The main block of the programmable timer is a 16-bit counter with its related auto-reload register. The counter can count up but also down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC):
- Auto-Reload Register (TIMx\_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

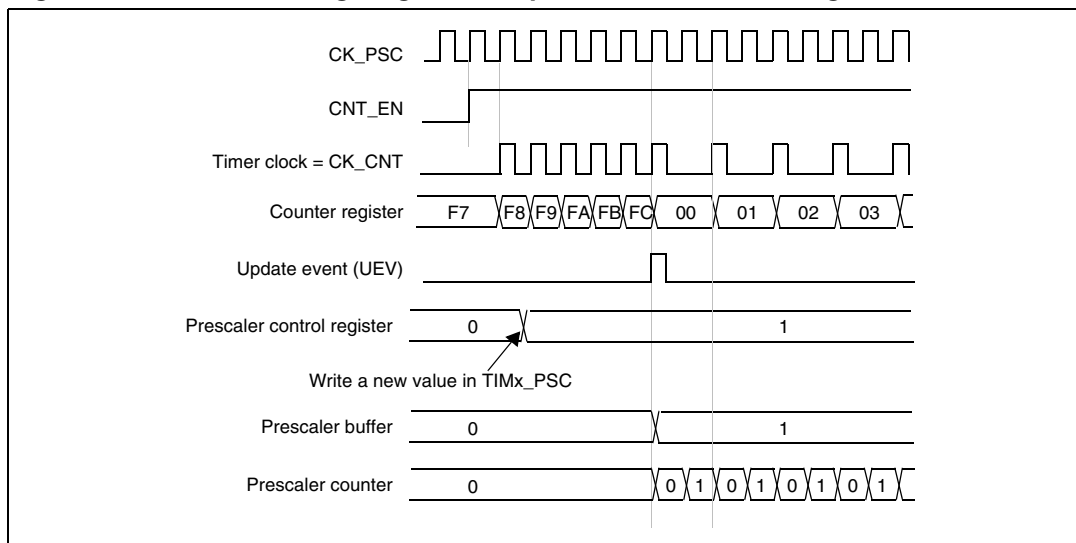

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

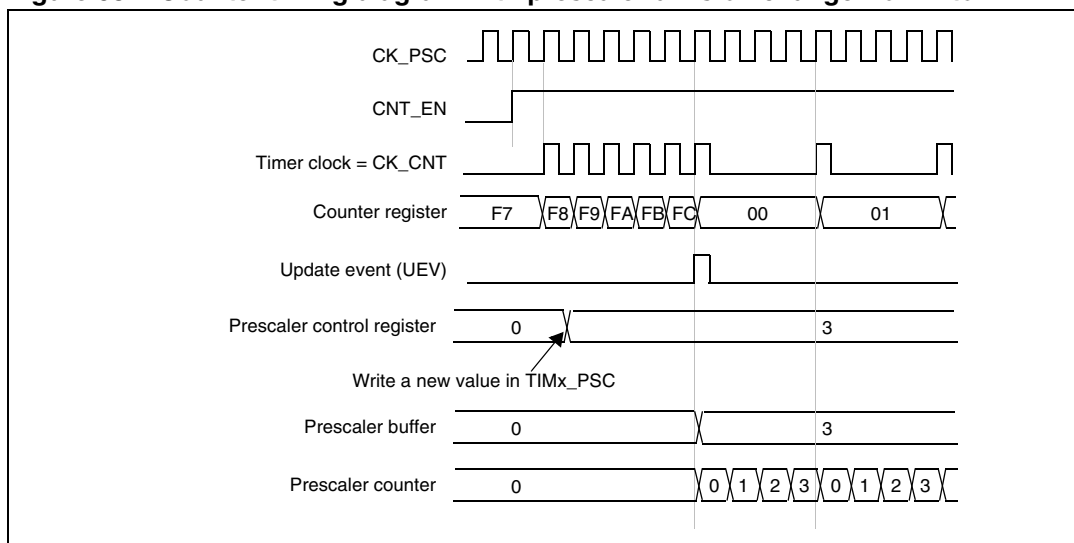

Figure 67 and Figure 68 give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 67. Counter timing diagram with prescaler division change from 1 to 2**

**Figure 68. Counter timing diagram with prescaler division change from 1 to 4**

### 13.3.2 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

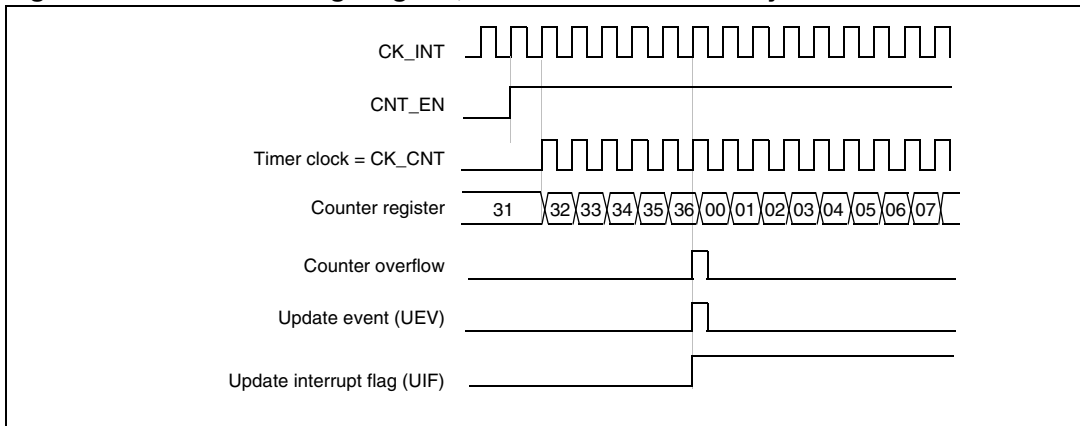

The UEV event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

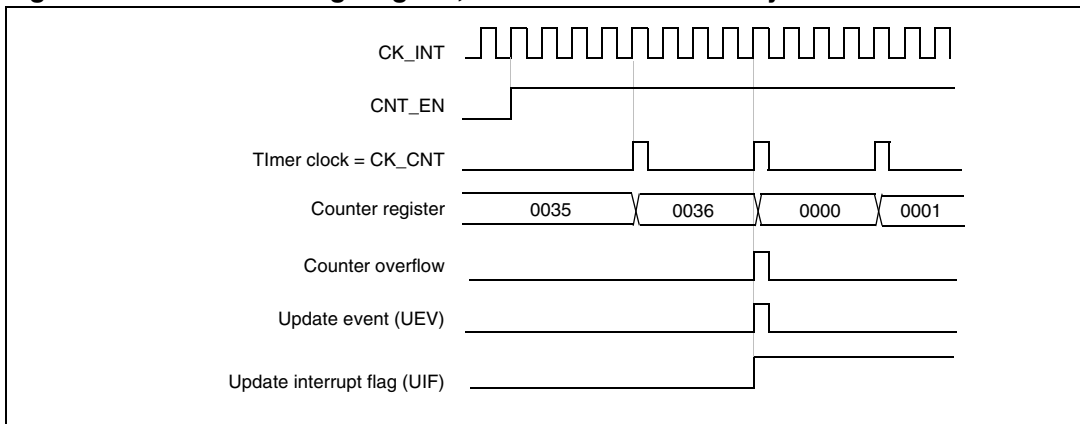

**Figure 69. Counter timing diagram, internal clock divided by 1**

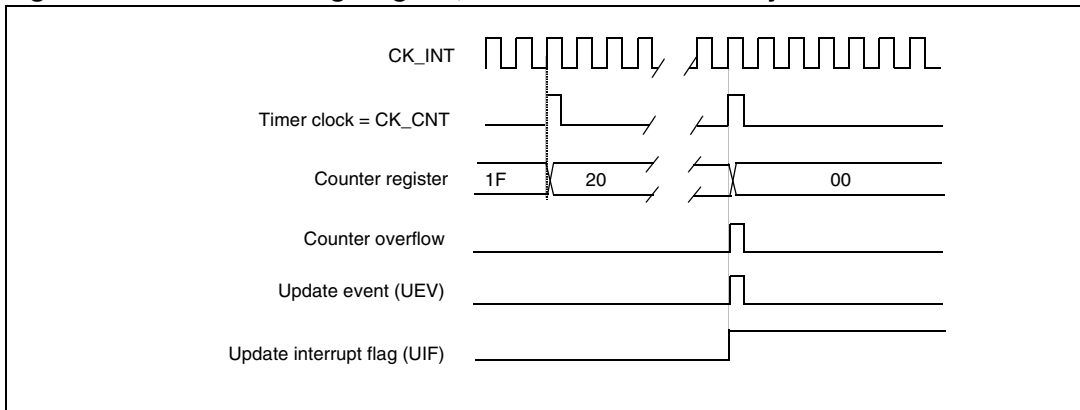

**Figure 70. Counter timing diagram, internal clock divided by 2**

**Figure 71. Counter timing diagram, internal clock divided by 4**

**Figure 72. Counter timing diagram, internal clock divided by N**

**Figure 73. Counter timing diagram, Update event when ARPE=0 (TIMx\_ARR not preloaded)**

**Figure 74. Counter timing diagram, Update event when ARPE=1 (TIMx\_ARR preloaded)**

**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx\_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generate at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller)

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

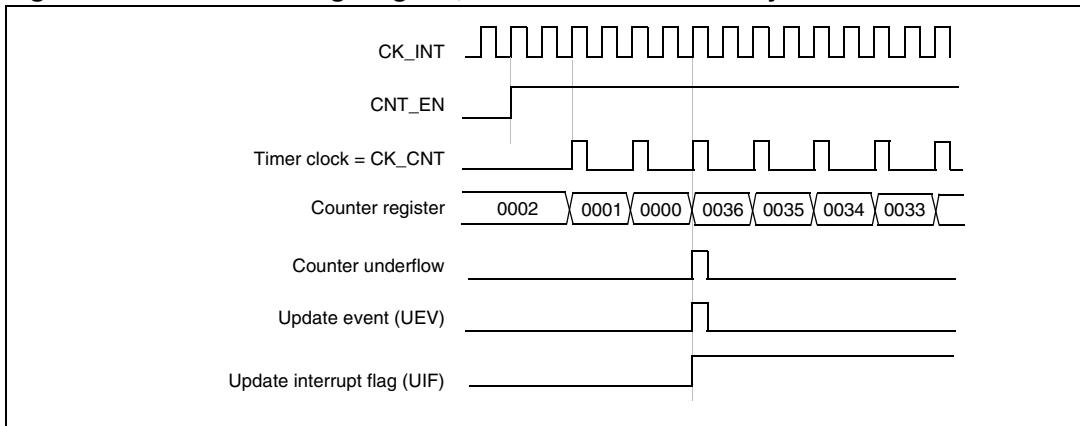

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

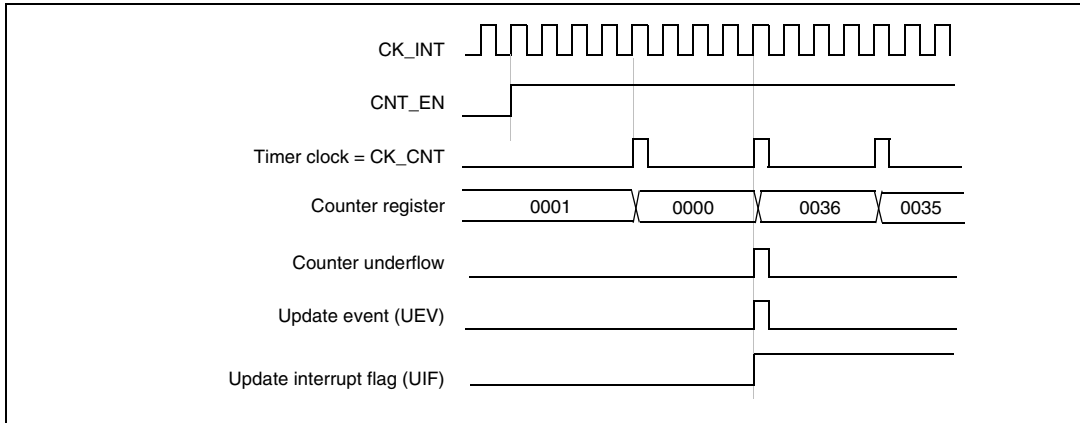

**Figure 75. Counter timing diagram, internal clock divided by 1**

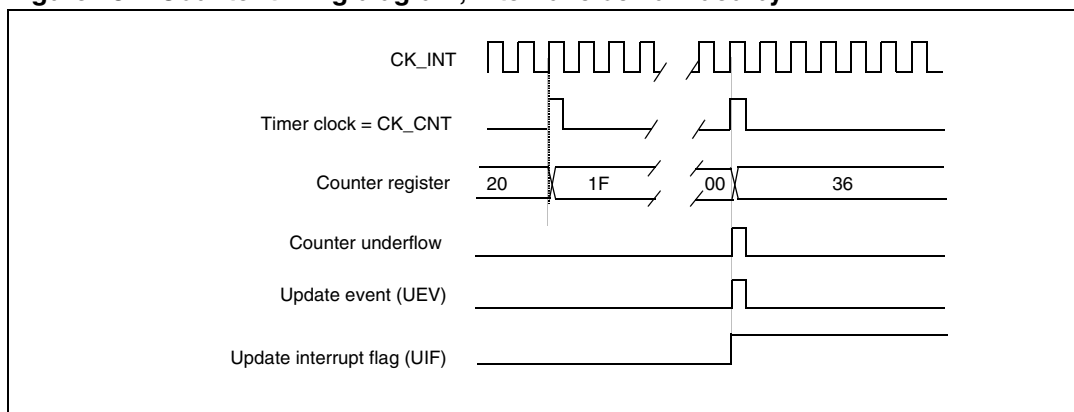

**Figure 76. Counter timing diagram, internal clock divided by 2**

**Figure 77. Counter timing diagram, internal clock divided by 4**

**Figure 78. Counter timing diagram, internal clock divided by N**

**Figure 79. Counter timing diagram, Update event when repetition counter is not used**

**Center-aligned mode (up/down counting)**

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx\_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

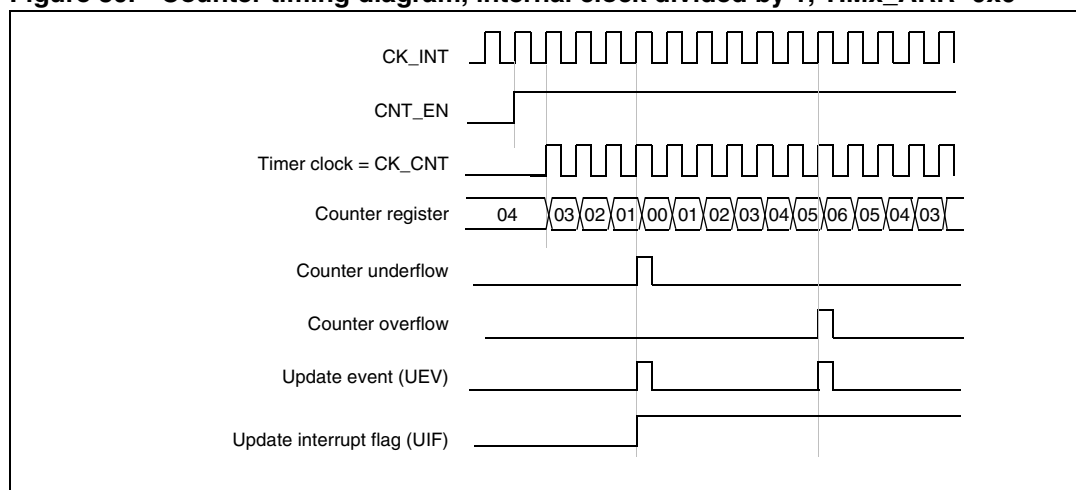

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

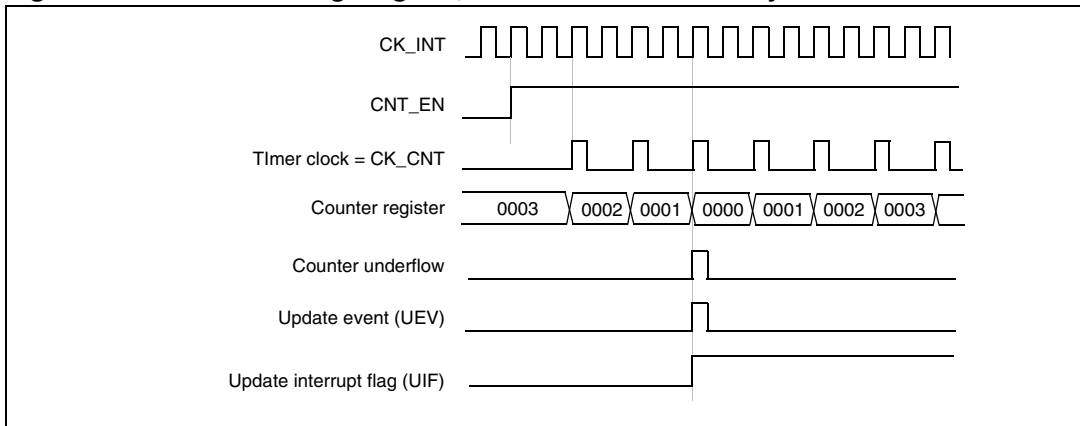

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 80. Counter timing diagram, internal clock divided by 1, TIMx\_ARR=0x6**

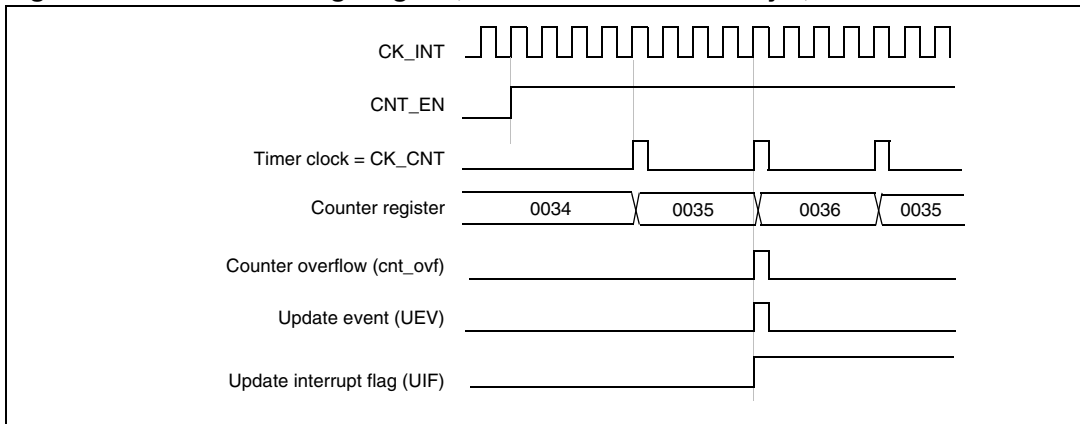

1. Here, center-aligned mode 1 is used (for more details refer to [Section 13.4.1: TIMx control register 1 \(TIMx\\_CR1\) on page 306](#)).

**Figure 85. Counter timing diagram, Update event with ARPE=1 (counter overflow)**

### 13.3.3 Clock selection

The counter clock can be provided by the following clock sources:

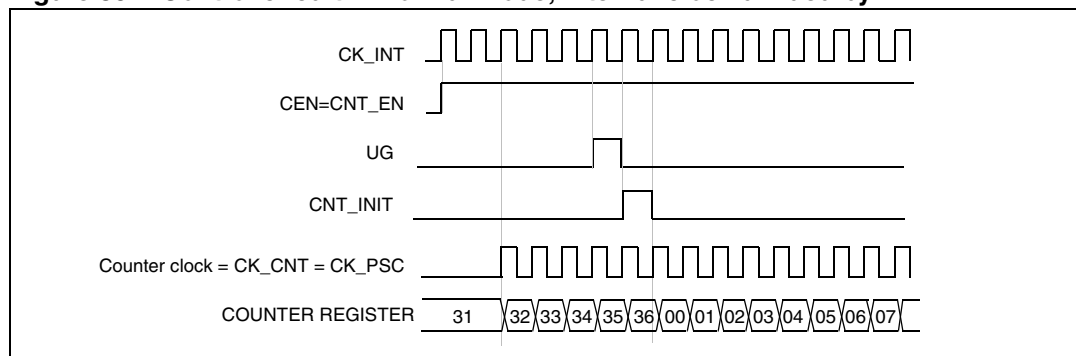

- Internal clock (CK\_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, you can configure Timer 3 to act as a prescaler for Timer 2. Refer to : [Using one timer as prescaler for another on page 301](#) for more details.

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx\_SMCR register), then the CEN, DIR (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 86](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

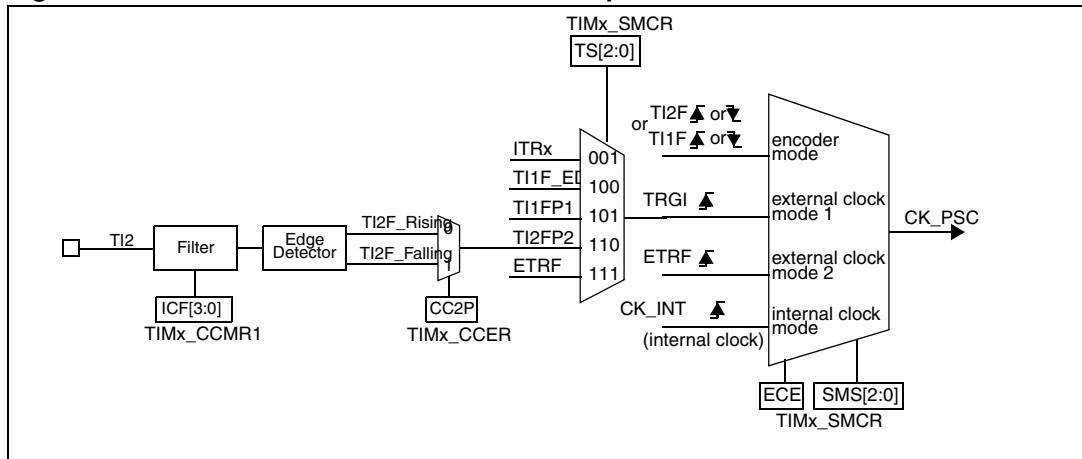

**Figure 86. Control circuit in normal mode, internal clock divided by 1**

#### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

**Figure 87. TI2 external clock connection example**

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S= '01 in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).

*Note:*

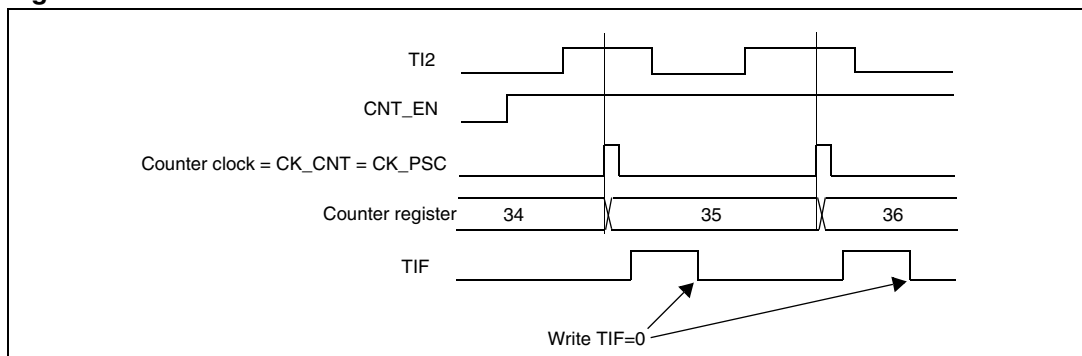

*The capture prescaler is not used for triggering, so you don't need to configure it.*

3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 88. Control circuit in external clock mode 1**

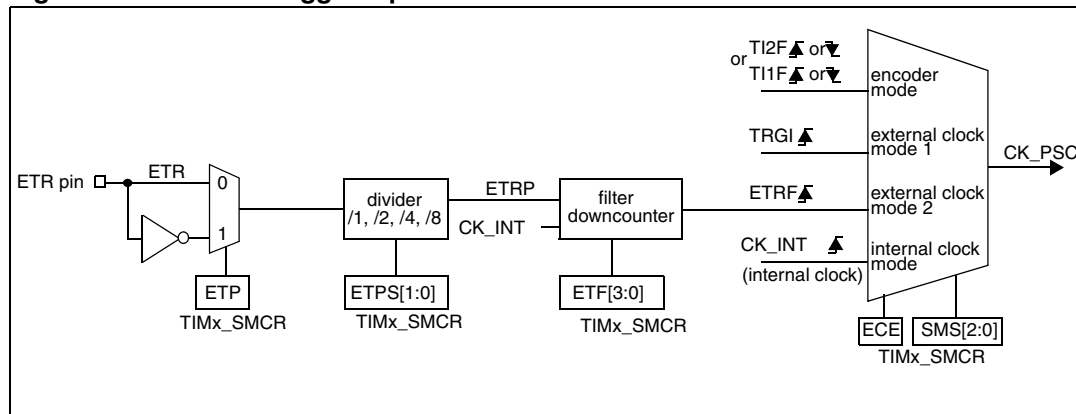

### External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The [Figure 89](#) gives an overview of the external trigger input block.

**Figure 89. External trigger input block**

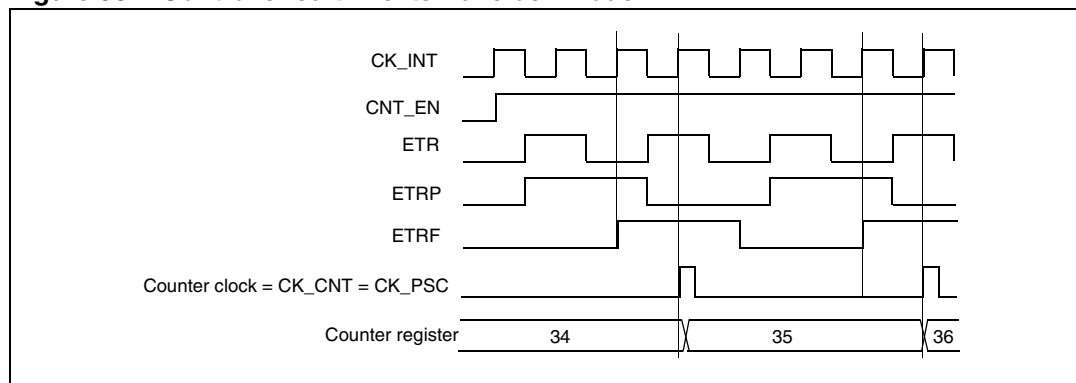

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx\_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx\_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

**Figure 90. Control circuit in external clock mode 2**

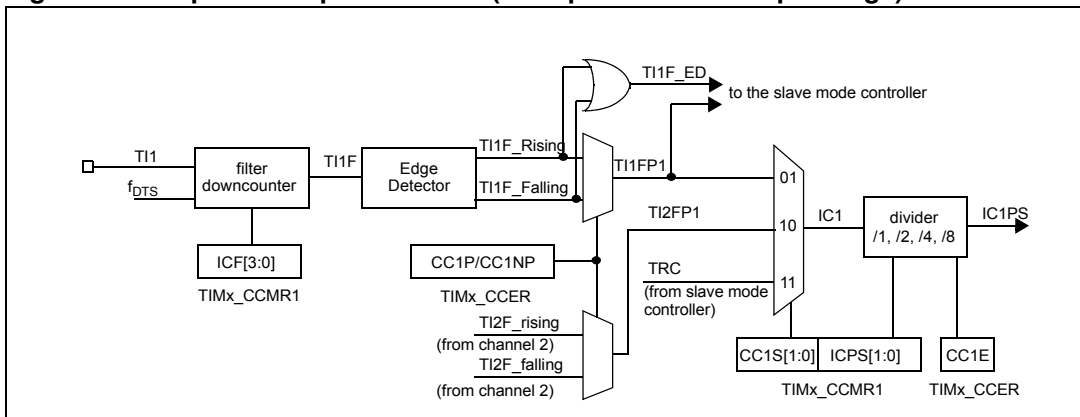

### 13.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

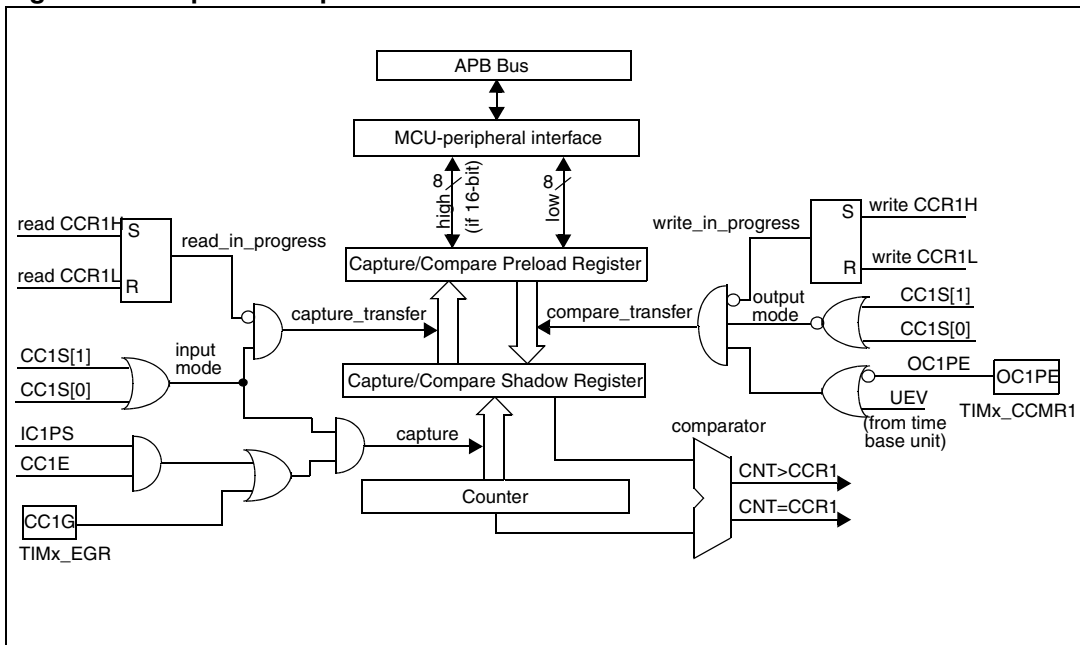

The input stage samples the corresponding Tix input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

**Figure 91. Capture/compare channel (example: channel 1 input stage)**

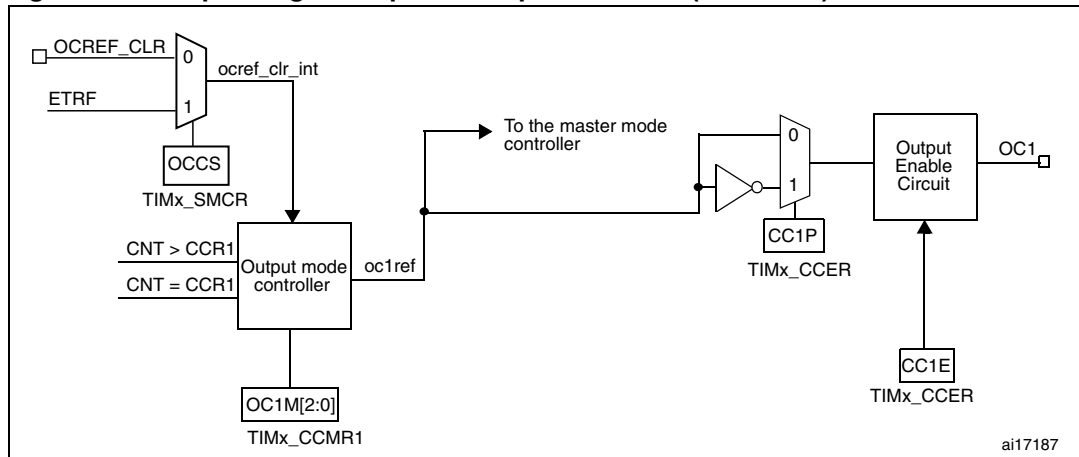

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 92. Capture/compare channel 1 main circuit**

**Figure 93. Output stage of capture/compare channel (channel 1)**

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 13.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when you write it to 0.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
- Program the input filter duration you need with respect to the signal you connect to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
- Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP bits to 00 in the TIMx\_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx\_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 13.3.6 PWM input mode

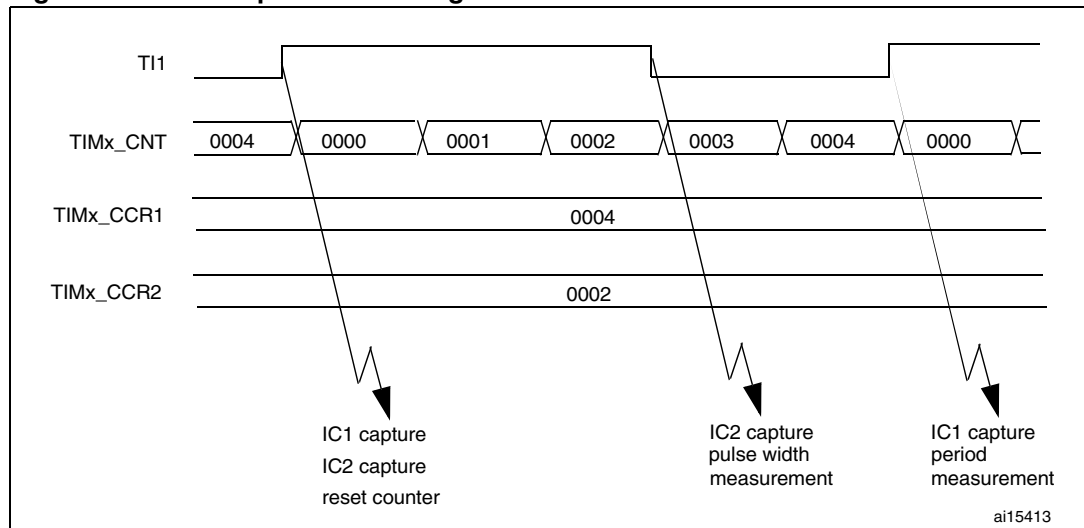

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same T1x input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two T1xFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, you can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on T11 using the following procedure (depending on CK\_INT frequency and prescaler value):

- Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P to '0' and the CC1NP bit to '0' (active on rising edge).
- Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P bit to '1' and the CC2NP bit to '0' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 94. PWM input mode timing**

### 13.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, you just need to write 101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

### 13.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

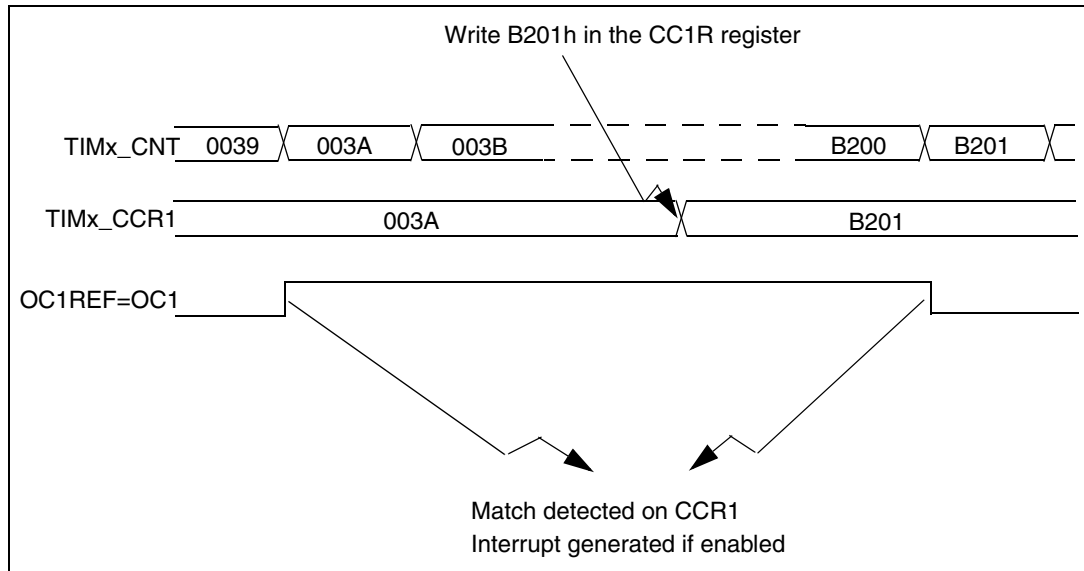

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, you must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 95](#).

**Figure 95. Output compare mode, toggle on OC1.**

### 13.3.9 PWM mode

Pulse width modulation mode allows you to generate a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or '111 (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. You must enable the corresponding preload register by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, you have to initialize all the registers by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx\_CCER register. Refer to the TIMx\_CCERx register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter). However, to comply with the OCREF\_CLR functionality (OCREF can be cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- When the result of the comparison changes, or
- When the output compare mode (OCxM bits in TIMx\_CCMRx register) switches from the "frozen" configuration (no comparison, OCxM='000) to one of the PWM modes (OCxM='110 or '111).

This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

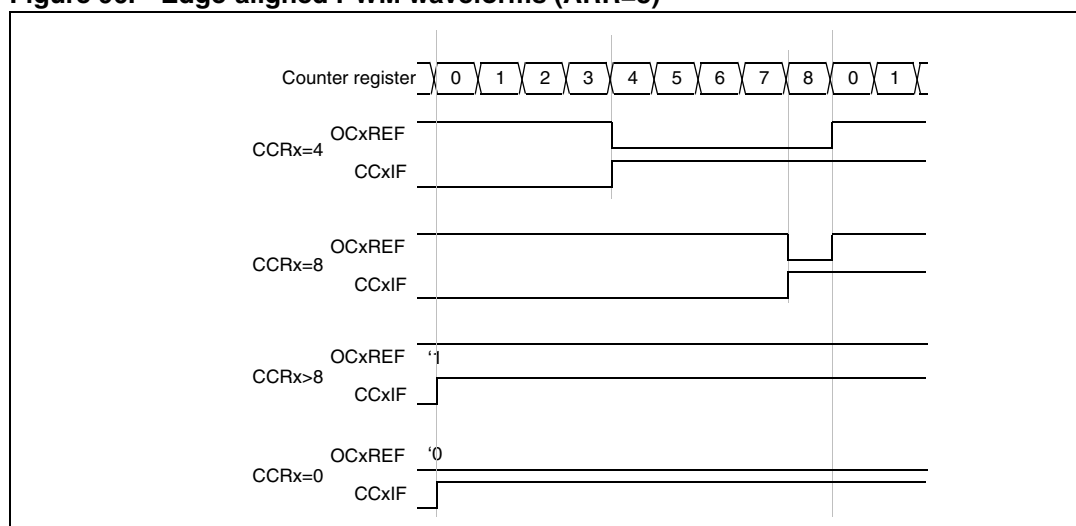

### PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low. Refer to the [Section : Upcounting mode on page 273](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxREF is held at '0'. [Figure 96](#) shows some edge-aligned PWM waveforms in an example where  $TIMx\_ARR=8$ .

**Figure 96. Edge-aligned PWM waveforms (ARR=8)**

### Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high. Refer to [Downcounting mode on page 276](#)

In PWM mode 1, the reference signal ocxref is low as long as  $TIMx\_CNT > TIMx\_CCRx$  else it becomes high. If the compare value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, then ocxref is held at '1'. 0% PWM is not possible in this mode.

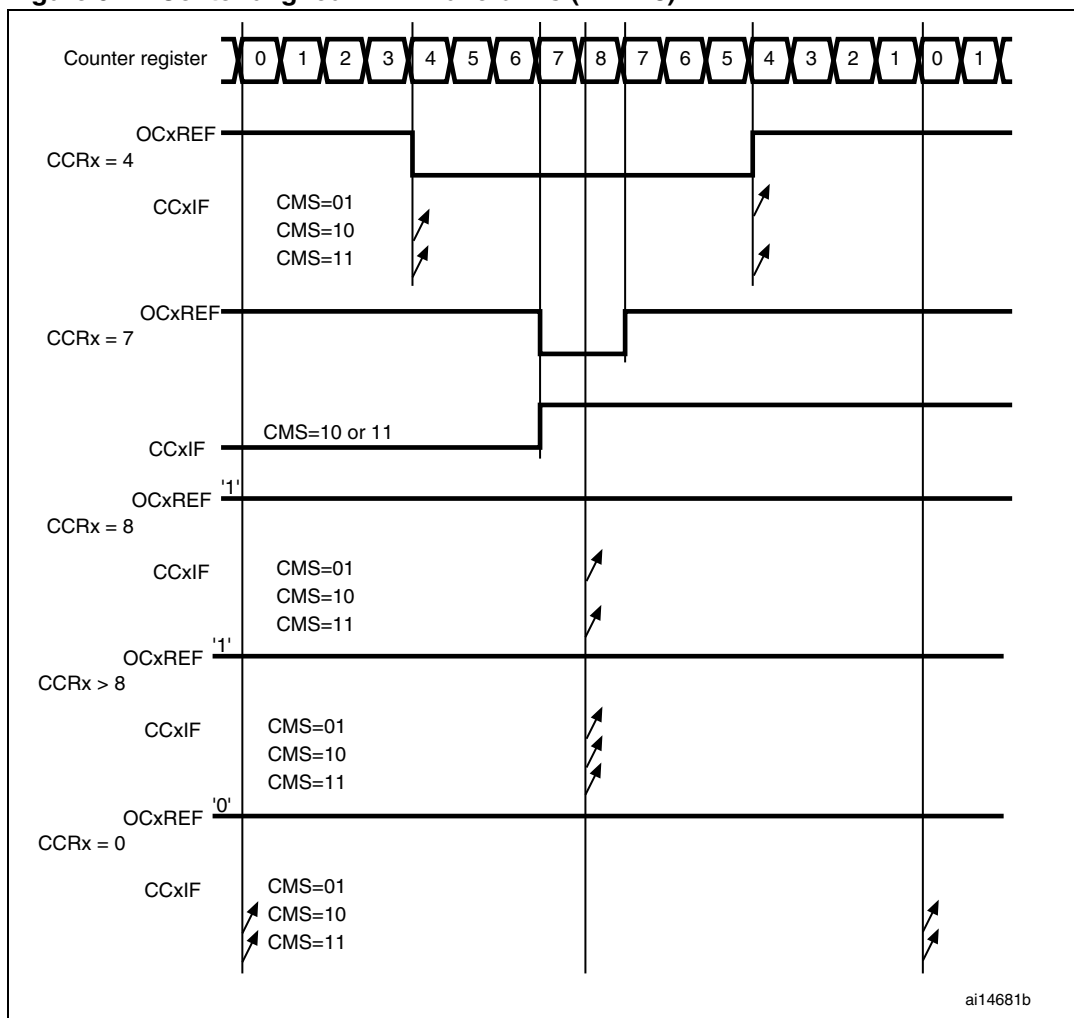

### PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are different from '00 (all the remaining configurations having the same effect on the ocxref/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx\_CR1 register is updated by hardware and must not be changed by software. Refer to the [Center-aligned mode \(up/down counting\) on page 278](#).

Figure 97 shows some center-aligned PWM waveforms in an example where:

- TIMx\_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx\_CR1 register.

Figure 97. Center-aligned PWM waveforms (ARR=8)

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx\_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if you write a value in the counter that is greater than the auto-reload value (TIMx\_CNT>TIMx\_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if you write 0 or write the TIMx\_ARR value in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### 13.3.10 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. You select One-pulse mode by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting:  $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ ),
- In downcounting:  $CNT > CCRx$ .

**Figure 98. Example of one-pulse mode.**

For example you may want to generate a positive pulse on OC1 with a length of  $t_{PULSE}$  and after a delay of  $t_{DELAY}$  as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

- Map TI2FP2 on TI2 by writing IC2S=01 in the TIMx\_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx\_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx\_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to '110 in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let's say you want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this you enable PWM mode 2 by writing OC1M=111 in the TIMx\_CCMR1 register. You can optionally enable the preload registers by writing OC1PE=1 in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case you have to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

You only want 1 pulse(Single mode), so you write '1' in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive Mode is selected.

#### Particular case: OCx fast enable:

In One-pulse mode, the edge detection on Tlx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY}}$  min we can get.

If you want to output a waveform with the minimum delay, you can set the OCxFE bit in the TIMx\_CCMRx register. Then OCxRef (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 13.3.11 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on OCREF\_CLR\_INPUT (OCxCE enable bit in the corresponding TIMx\_CCMRx register set to 1). OCxREF remains low until the next update event UEV occurs. This function can only be used in the output compare and PWM modes. It does not work in forced mode.

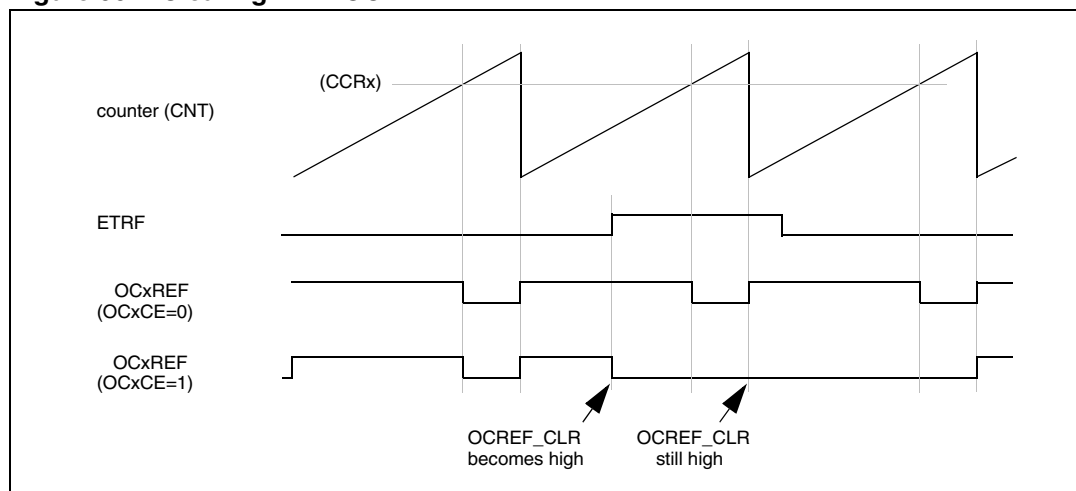

OCREF\_CLR\_INPUT can be selected between the OCREF\_CLR input and ETRF (ETR after the filter) by configuring the OCCS bit in the TIMx\_SMCR register.

When ETRF is chosen, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx\_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1\_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

*Figure 99* shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

Figure 99. Clearing TIMx OCxREF

*Note:* In case of a PWM with a 100% duty cycle (if  $CCR_x > ARR$ ),  $OCxREF$  is enabled again at the next counter overflow.

### 13.3.12 Encoder interface mode

To select Encoder Interface mode write  $SMS=001$  in the  $TIMx\_SMCR$  register if the counter is counting on TI2 edges only,  $SMS=010$  if it is counting on TI1 edges only and  $SMS=011$  if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the  $TIMx\_CCER$  register. CC1NP and CC2NP must be kept cleared. When needed, you can program the input filter as well.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to [Table 52](#). The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in  $TIMx\_CR1$  register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the  $TIMx\_CR1$  register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the  $TIMx\_ARR$  register (0 to ARR or ARR down to 0 depending on the direction). So you must configure  $TIMx\_ARR$  before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 don't switch at the same time.

**Table 52. Counting direction versus encoder signals**

Active edge	Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1)	TI1FP1 signal		TI2FP2 signal	
		Rising	Falling	Rising	Falling
Counting on TI1 only	High	Down	Up	No Count	No Count
	Low	Up	Down	No Count	No Count
Counting on TI2 only	High	No Count	No Count	Up	Down
	Low	No Count	No Count	Down	Up
Counting on TI1 and TI2	High	Down	Up	Up	Down
	Low	Up	Down	Down	Up

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The [Figure 100](#) gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx\_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= 01 (TIMx\_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P=0, CC1NP = ‘0 (TIMx\_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P=0, CC2NP = ‘0 (TIMx\_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= 011 (TIMx\_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx\_CR1 register, Counter is enabled)

**Figure 100. Example of counter operation in encoder interface mode.**

Figure 101 gives an example of counter behavior when IC1FP1 polarity is inverted (same configuration as above except CC1P=1).

**Figure 101. Example of encoder interface mode with IC1FP1 polarity inverted.**

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. You can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. You can do this by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

### 13.3.13 Timer input XOR function

The TI1S bit in the TIMx\_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx\_CH1 to TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

### 13.3.14 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don’t need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you don’t need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write

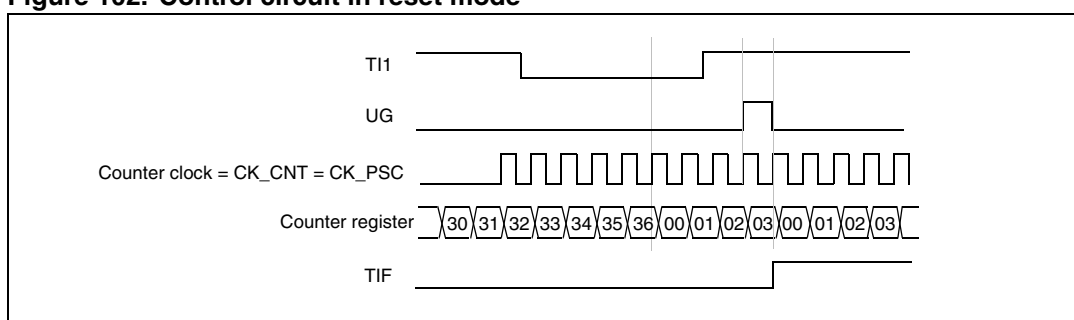

CC1P=0 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect rising edges only).

- Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 102. Control circuit in reset mode**

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

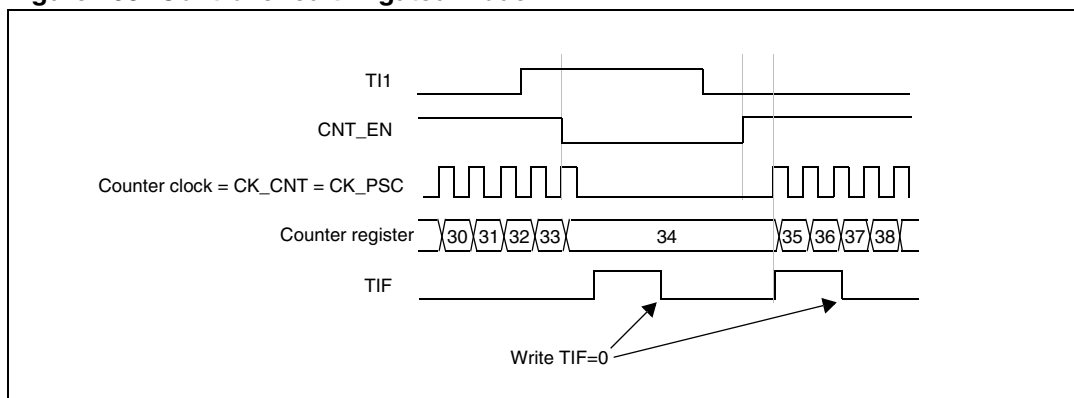

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you don't need to configure it. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 103. Control circuit in gated mode**

*Note:* The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

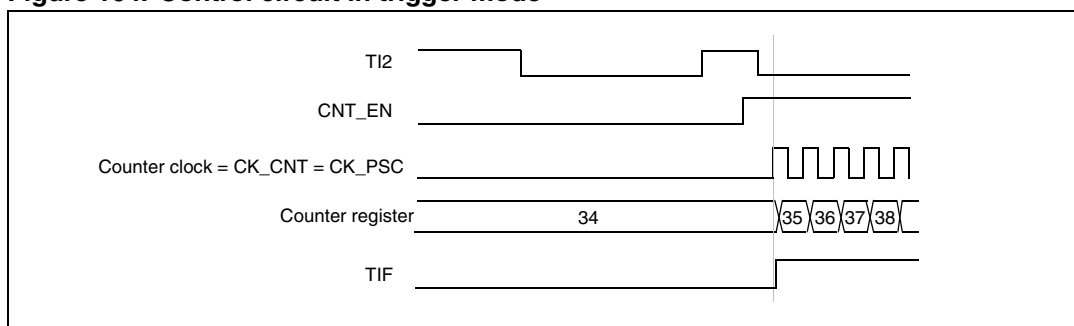

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don’t need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so you don’t need to configure it. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 104. Control circuit in trigger mode**

**Slave mode: External Clock mode 2 + trigger mode**

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode,

gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

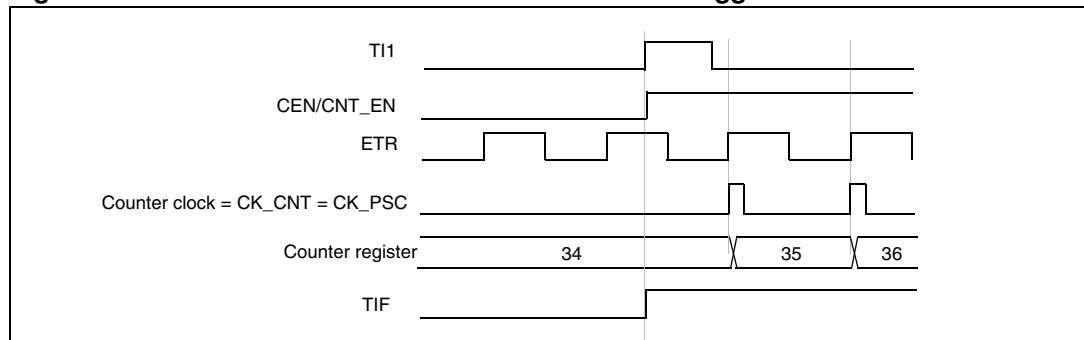

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx\_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS=00: prescaler disabled
  - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI1:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx\_CCMR1 register to select only the input capture source
  - CC1P=0 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 105. Control circuit in external clock mode 2 + trigger mode**

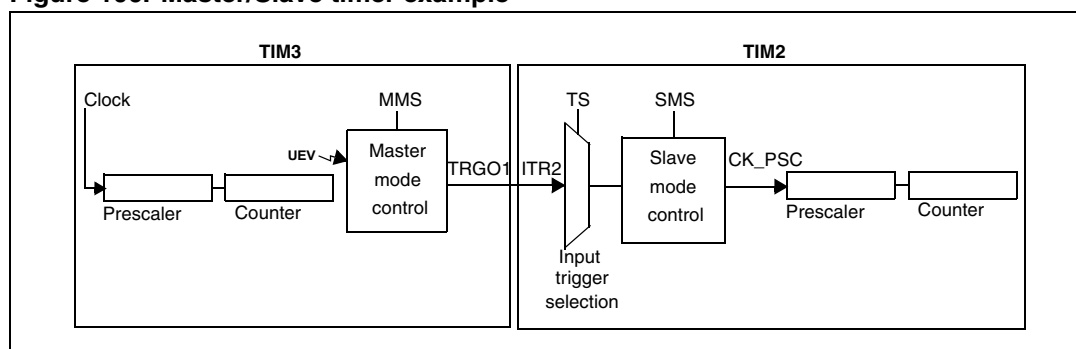

### 13.3.15 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

*Figure 106: Master/Slave timer example* presents an overview of the trigger selection and the master mode selection blocks.

## Using one timer as prescaler for another

**Figure 106. Master/Slave timer example**

For example, you can configure TIM3 to act as a prescaler for TIM2. Refer to [Figure 106](#). To do this:

- Configure TIM3 in master mode so that it outputs a periodic trigger signal on each update event UEV. If you write MMS=010 in the TIM3\_CR2 register, a rising edge is output on TRGO1 each time an update event is generated.
- To connect the TRGO1 output of TIM3 to TIM2, TIM2 must be configured in slave mode using ITR2 as internal trigger. You select this through the TS bits in the TIM2\_SMCR register (writing TS=000).
- Then you put the slave mode controller in external clock mode 1 (write SMS=111 in the TIM2\_SMCR register). This causes TIM2 to be clocked by the rising edge of the periodic TIM3 trigger signal (which correspond to the TIM3 counter overflow).
- Finally both timers must be enabled by setting their respective CEN bits (TIMx\_CR1 register).

*Note:* If OCx is selected on TIM3 as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM2.

## Using one timer to enable another timer

In this example, we control the enable of TIM2 with the output compare 1 of Timer 3. Refer to [Figure 106](#) for connections. TIM2 counts on the divided internal clock only when OC1REF of TIM3 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3\_CR2 register).
- Configure the TIM3 OC1REF waveform (TIM3\_CCMR1 register).
- Configure TIM2 to get the input trigger from TIM3 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in gated mode (SMS=101 in TIM2\_SMCR register).
- Enable TIM2 by writing '1' in the CEN bit (TIM2\_CR1 register).
- Start TIM3 by writing '1' in the CEN bit (TIM3\_CR1 register).

*Note:* The counter 2 clock is not synchronized with counter 1, this mode only affects the TIM2 counter enable signal.

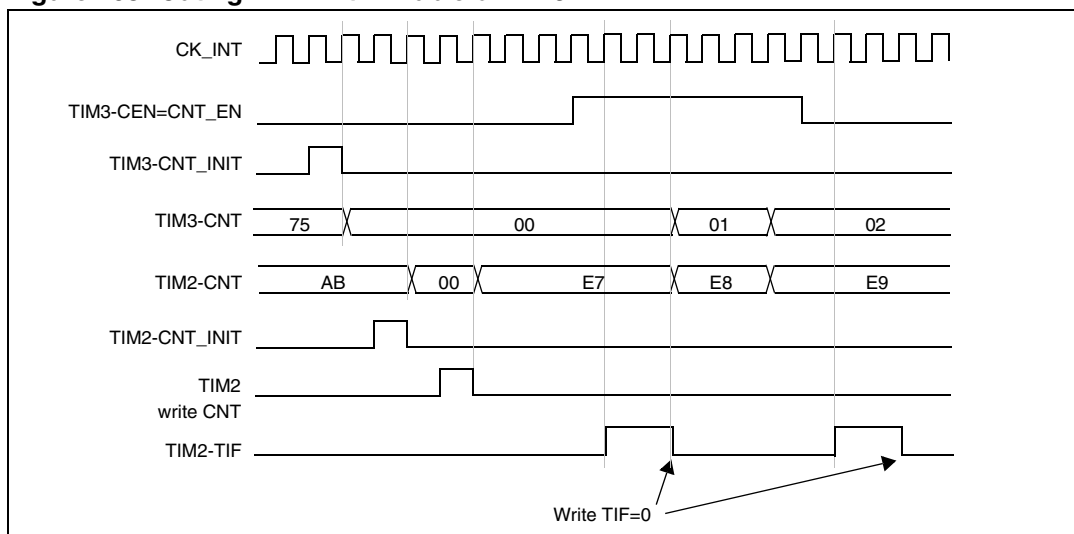

**Figure 107. Gating TIM2 with OC1REF of TIM3**

In the example in [Figure 107](#), the TIM2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM3. You can then write any value you want in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx\_EGR registers.

In the next example, we synchronize TIM3 and TIM2. TIM3 is the master and starts from 0. TIM2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM2 stops when TIM3 is disabled by writing '0' to the CEN bit in the TIM3\_CR1 register:

- Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3\_CR2 register).
- Configure the TIM3 OC1REF waveform (TIM3\_CCMR1 register).
- Configure TIM2 to get the input trigger from TIM3 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in gated mode (SMS=101 in TIM2\_SMCR register).
- Reset TIM3 by writing '1' in UG bit (TIM3\_EGR register).
- Reset TIM2 by writing '1' in UG bit (TIM2\_EGR register).
- Initialize TIM2 to 0xE7 by writing '0xE7' in the TIM2 counter (TIM2\_CNT).
- Enable TIM2 by writing '1' in the CEN bit (TIM2\_CR1 register).
- Start TIM3 by writing '1' in the CEN bit (TIM3\_CR1 register).
- Stop TIM3 by writing '0' in the CEN bit (TIM3\_CR1 register).

**Figure 108. Gating TIM2 with Enable of TIM3**

**Using one timer to start another timer**

In this example, we set the enable of Timer 2 with the update event of Timer 3. Refer to [Figure 106](#) for connections. Timer 2 starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0 to the CEN bit in the TIM2\_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

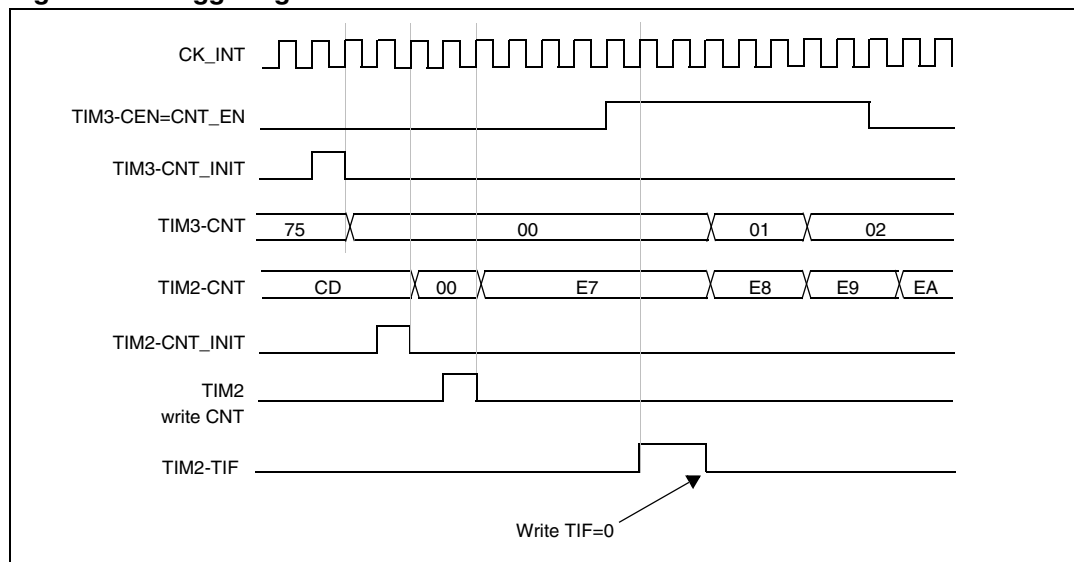

- Configure TIM3 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM3\_CR2 register).
- Configure the TIM3 period (TIM3\_ARR registers).
- Configure TIM2 to get the input trigger from TIM3 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in trigger mode (SMS=110 in TIM2\_SMCR register).
- Start TIM3 by writing '1 in the CEN bit (TIM3\_CR1 register).

**Figure 109. Triggering TIM2 with update of TIM3**

As in the previous example, you can initialize both counters before starting counting. [Figure 110](#) shows the behavior with the same configuration as in [Figure 109](#) but in trigger mode instead of gated mode (SMS=110 in the TIM2\_SMCR register).

**Figure 110. Triggering TIM2 with Enable of TIM3**

### Using one timer as prescaler for another timer

For example, you can configure TIM3 to act as a prescaler for TIM2. Refer to [Figure 106](#) for connections. To do this:

- Configure TIM3 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM3\_CR2 register). then it outputs a periodic signal on each counter overflow.
- Configure the TIM3 period (TIM3\_ARR registers).
- Configure TIM2 to get the input trigger from TIM3 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in external clock mode 1 (SMS=111 in TIM2\_SMCR register).
- Start TIM2 by writing '1 in the CEN bit (TIM2\_CR1 register).
- Start TIM3 by writing '1 in the CEN bit (TIM3\_CR1 register).

### Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM3 when its TI1 input rises, and the enable of TIM2 with the enable of TIM3. Refer to [Figure 106](#) for connections. To ensure the counters are aligned, TIM3 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to TIM2):

- Configure TIM3 master mode to send its Enable as trigger output (MMS=001 in the TIM3\_CR2 register).
- Configure TIM3 slave mode to get the input trigger from TI1 (TS=100 in the TIM3\_SMCR register).
- Configure TIM3 in trigger mode (SMS=110 in the TIM3\_SMCR register).
- Configure the TIM3 in Master/Slave mode by writing MSM=1 (TIM3\_SMCR register).

- Configure TIM2 to get the input trigger from TIM3 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in trigger mode (SMS=110 in the TIM2\_SMCR register).

When a rising edge occurs on T11 (TIM3), both counters starts counting synchronously on the internal clock and both TIF flags are set.

*Note:* In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but you can easily insert an offset between them by writing any of the counter registers (TIMx\_CNT). You can see that the master/slave mode insert a delay between CNT\_EN and CK\_PSC on TIM3.

**Figure 111. Triggering TIM3 and TIM2 with TIM3 TI1 input**

### 13.3.16 Debug mode

When the microcontroller enters debug mode (Cortex-M3 core - halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBGMCU module. For more details, refer to [Section 24.16.2: Debug support for timers, watchdog and I2C](#).

## 13.4 TIMx registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 13.4.1 TIMx control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CKD[1:0]		ARPE	CMS		DIR	OPM	URS	UDIS	CEN
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:10 Reserved, always read as 0

Bits 9:8 **CKD**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (ETR, TIX),

- 00:  $t_{DTS} = t_{CK\_INT}$
- 01:  $t_{DTS} = 2 \times t_{CK\_INT}$
- 10:  $t_{DTS} = 4 \times t_{CK\_INT}$
- 11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

- 0: TIMx\_ARR register is not buffered
- 1: TIMx\_ARR register is buffered

Bits 6:5 **CMS**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*

Bit 4 **DIR**: Direction

- 0: Counter used as upcounter
- 1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One-pulse mode

- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the bit CEN)

**Bit 2 URS:** Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

**Bit 1 UDIS:** Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

**Bit 0 CEN:** Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

### 13.4.2 TIMx control register 2 (TIMx\_CR2)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								TI1S	MMS[2:0]			CCDS	Reserved			
								rw	rw	rw	rw	rw				

Bits 15:8 Reserved, always read as 0.

Bit 7 **TI1S**: T11 selection

0: The TIMx\_CH1 pin is connected to T11 input

1: The TIMx\_CH1, CH2 and CH3 pins are connected to the T11 input (XOR combination)

Bits 6:4 **MMS**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO)

100: **Compare** - OC1REF signal is used as trigger output (TRGO)

101: **Compare** - OC2REF signal is used as trigger output (TRGO)

110: **Compare** - OC3REF signal is used as trigger output (TRGO)

111: **Compare** - OC4REF signal is used as trigger output (TRGO)

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bits 2:0 Reserved, always read as 0

### 13.4.3 TIMx slave mode control register (TIMx\_SMCR)

Address offset: 0x08

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS[1:0]		ETF[3:0]				MSM	TS[2:0]			OCCS	SMS[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{ETR}$  is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge

1: ETR is inverted, active at low level or falling edge

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

**1**: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).

**2**: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).

**3**: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

Bits 13:12 **ETPS**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of CK\_INT frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

00: Prescaler OFF

01: ETRP frequency divided by 2

10: ETRP frequency divided by 4

11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bit 7 **MSM**: Master/Slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0).

001: Internal Trigger 1 (ITR1).

010: Internal Trigger 2 (ITR2).

011: Internal Trigger 3 (ITR3).

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

111: External Trigger input (ETRF)

See [Table 53: TIMx internal trigger connection on page 311](#) for more details on ITRx meaning for each Timer.

*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

Bit 3 **OCCS**: OCREF clear selection

This bit is used to select the OCREF clear source

0: OCREF\_CLR\_INT is connected to the OCREF\_CLR input

1: OCREF\_CLR\_INT is connected to ETRF

Bits 2:0 **SMS**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

000: Slave mode disabled - if CEN = '1 then the prescaler is clocked directly by the internal clock.

001: Encoder mode 1 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.

010: Encoder mode 2 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.

011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS=100). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

**Table 53. TIMx internal trigger connection**

Slave TIM	ITR0 (TS = 000)	ITR1 (TS = 001)	ITR2 (TS = 010)	ITR3 (TS = 011)
<b>TIM2</b>	TIM9	TIM10	TIM3	TIM4
<b>TIM3</b>	TIM9	TIM2	TIM11	TIM4
<b>TIM4</b>	TIM10	TIM2	TIM3	TIM9

### 13.4.4 TIMx DMA/Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- Bit 4 **CC4IE**: Capture/Compare 4 interrupt enable  
0: CC4 interrupt disabled  
1: CC4 interrupt enabled

- Bit 3 **CC3IE**: Capture/Compare 3 interrupt enable  
 0: CC3 interrupt disabled  
 1: CC3 interrupt enabled
- Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable  
 0: CC2 interrupt disabled  
 1: CC2 interrupt enabled
- Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable  
 0: CC1 interrupt disabled  
 1: CC1 interrupt enabled
- Bit 0 **UIE**: Update interrupt enable  
 0: Update interrupt disabled  
 1: Update interrupt enabled

### 13.4.5 TIMx status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved				CC4OF	CC3OF	CC2OF	CC1OF	Reserved		TIF	Res	CC4IF	CC3IF	CC2IF	CC1IF	UIF
				rc_w0	rc_w0	rc_w0	rc_w0			rc_w0		rc_w0	rc_w0	rc_w0	rc_w0	rc_w0

- Bit 15:13 Reserved, always read as 0.
- Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag  
refer to CC1OF description
- Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag  
refer to CC1OF description
- Bit 10 **CC2OF**: Capture/compare 2 overcapture flag  
refer to CC1OF description
- Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.  
 0: No overcapture has been detected  
 1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set
- Bits 8:7 Reserved, always read as 0.
- Bit 6 **TIF**: Trigger interrupt flag  
 This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.  
 0: No trigger event occurred  
 1: Trigger interrupt pending
- Bit 5 Reserved, always read as 0
- Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag  
refer to CC1IF description

- Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag  
refer to CC1IF description
- Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag  
refer to CC1IF description
- Bit 1 **CC1IF**: Capture/compare 1 interrupt flag  
**If channel CC1 is configured as output:**  
This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx\_CR1 register description). It is cleared by software.  
0: No match  
1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)  
**If channel CC1 is configured as input:**  
This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.  
0: No input capture occurred  
1: The counter value has been captured in TIMx\_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)
- Bit 0 **UIF**: Update interrupt flag
- This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  - At overflow or underflow (for TIM2 to TIM4) and if UDIS=0 in the TIMx\_CR1 register.
  - When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.  
When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

### 13.4.6 TIMx event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									TG	Res.	CC4G	CC3G	CC2G	CC1G	UG
									w		w	w	w	w	

Bits 15:7 Reserved, always read as 0.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, always read as 0.

Bit 4 **CC4G**: Capture/compare 4 generation  
refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation  
refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation  
refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx\_ARR) if DIR=1 (downcounting).

### 13.4.7 TIMx capture/compare mode register 1 (TIMx\_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So you must take care that the same bit can have a different meaning for the input stage and for the output stage.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OC2CE	OC2M[2:0]			OC2PE	OC2FE	CC2S[1:0]		OC1CE	OC1M[2:0]			OC1PE	OC1FE	CC1S[1:0]	
IC2F[3:0]				IC2PSC[1:0]				IC1F[3:0]				IC1PSC[1:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

#### Output compare mode

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 14:12 **OC2M[2:0]**: Output compare 2 mode

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bit 7 **OC1CE**: Output compare 1 clear enable

OC1CE: Output Compare 1 Clear Enable

0: OC1Ref is not affected by the ETRF input

1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.(this mode is used to generate a timing base).

001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

100: Force inactive level - OC1REF is forced low.

101: Force active level - OC1REF is forced high.

110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF=0) as long as TIMx\_CNT>TIMx\_CCR1 else active (OC1REF=1).

111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active. In downcounting, channel 1 is active as long as TIMx\_CNT>TIMx\_CCR1 else inactive.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S=00 (the channel is configured in output).*

*2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S=00 (the channel is configured in output).*

*2: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10: CC1 channel is configured as input, IC1 is mapped on TI2.

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC2 channel is configured as output.

01: CC2 channel is configured as input, IC2 is mapped on TI2.

10: CC2 channel is configured as input, IC2 is mapped on TI1.

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bits 7:4 **IC1F**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

*Note: In current silicon revision,  $f_{DTS}$  is replaced in the formula by  $CK\_INT$  when  $ICx\{F[3:0]\}=1, 2$  or  $3$ .*

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).

The prescaler is reset as soon as  $CC1E=0$  (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

### 13.4.8 TIMx capture/compare mode register 2 (TIMx\_CCMR2)

Address offset: 0x1C

Reset value: 0x0000

Refer to the above CCMR1 register description.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OC4CE	OC4M[2:0]			OC4PE	OC4FE	CC4S[1:0]		OC3CE	OC3M[2:0]			OC3PE	OC3FE	CC3S[1:0]	
IC4F[3:0]				IC4PSC[1:0]				IC3F[3:0]				IC3PSC[1:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

#### Output compare mode

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 14:12 **OC4M**: Output compare 4 mode

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 6:4 **OC3M**: Output compare 3 mode

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

**Input capture mode**

Bits 15:12 **IC4F**: Input capture 4 filter

Bits 11:10 **IC4PSC**: Input capture 4 prescaler

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bits 7:4 **IC3F**: Input capture 3 filter

Bits 3:2 **IC3PSC**: Input capture 3 prescaler

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

**13.4.9 TIMx capture/compare enable register (TIMx\_CCER)**

Address offset: 0x20

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw		rw	rw	rw		rw	rw	rw		rw	rw	rw		rw	rw

Bit 15 **CC4NP**: Capture/Compare 4 output Polarity.

Refer to CC1NP description

Bit 14 Reserved, always read as 0.

Bit 13 **CC4P**: Capture/Compare 4 output Polarity.

refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable.

refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 output Polarity.

refer to CC1NP description

Bit 10 Reserved, always read as 0.

Bits 9:8 Reserved, always read as 0.

Bit 9 **CC3P**: Capture/Compare 3 output Polarity.

refer to CC1P description

- Bit 8 **CC3E**: *Capture/Compare 3 output enable.*  
refer to CC1E description
- Bit 7 **CC2NP**: *Capture/Compare 2 output Polarity.*  
refer to CC1NP description
- Bit 6 Reserved, always read as 0.
- Bit 5 **CC2P**: *Capture/Compare 2 output Polarity.*  
refer to CC1P description
- Bit 4 **CC2E**: *Capture/Compare 2 output enable.*  
refer to CC1E description
- Bit 3 **CC1NP**: *Capture/Compare 1 output Polarity.*  
  - CC1 channel configured as output:**  
CC1NP must be kept cleared in this case.
  - CC1 channel configured as input:**  
This bit is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity. refer to CC1P description.
- Bit 2 Reserved, always read as 0.
- Bit 1 **CC1P**: *Capture/Compare 1 output Polarity.*  
  - CC1 channel configured as output:**  
0: OC1 active high  
1: OC1 active low
  - CC1 channel configured as input:**  
CC1NP/CC1P bits select TI1FP1 and TI2FP1 polarity for trigger or capture operations.  
00: noninverted/rising edge : circuit is sensitive to TIxFP1 rising edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode, encoder mode).  
01: inverted/falling edge : circuit is sensitive to TIxFP1 falling edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is inverted (trigger in gated mode, encoder mode).  
10: reserved, do not use this configuration.  
11: noninverted/both edges: circuit is sensitive to both TIxFP1 rising and falling edges (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode). This configuration must not be used for encoder mode.
- Bit 0 **CC1E**: *Capture/Compare 1 output enable.*  
  - CC1 channel configured as output:**  
0: Off - OC1 is not active  
1: On - OC1 signal is output on the corresponding output pin
  - CC1 channel configured as input:**  
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.  
0: Capture disabled  
1: Capture enabled

**Table 54. Output control bit for standard OCx channels**

CCxE bit	OCx output state
0	Output Disabled (OCx=0, OCx_EN=0)
1	OCx=OCxREF + Polarity, OCx_EN=1

Note: The state of the external IO pins connected to the standard OCx channels depends on the OCx channel state and the GPIO and AFIO registers.

### 13.4.10 TIMx counter (TIMx\_CNT)

Address offset: 0x24

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CNT[15:0]**: Counter value

### 13.4.11 TIMx prescaler (TIMx\_PSC)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event.

### 13.4.12 TIMx auto-reload register (TIMx\_ARR)

Address offset: 0x2C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the [Section 13.3.1: Time-base unit on page 271](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 13.4.13 TIMx capture/compare register 1 (TIMx\_CCR1)

Address offset: 0x34

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

### 13.4.14 TIMx capture/compare register 2 (TIMx\_CCR2)

Address offset: 0x38

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2).

### 13.4.15 TIMx capture/compare register 3 (TIMx\_CCR3)

Address offset: 0x3C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CCR3[15:0]**: Capture/Compare value

**If channel CC3 is configured as output:**

CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC3 output.

**If channel CC3 is configured as input:**

CCR3 is the counter value transferred by the last input capture 3 event (IC3).

### 13.4.16 TIMx capture/compare register 4 (TIMx\_CCR4)

Address offset: 0x40

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR4[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CCR4[15:0]**: Capture/Compare value

1/ if CC4 channel is configured as output (CC4S bits):

CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC4 output.

2/ if CC4 channel is configured as input (CC4S bits in TIMx\_CCMR4 register):

CCR4 is the counter value transferred by the last input capture 4 event (IC4).

### 13.4.17 TIMx DMA control register (TIMx\_DCR)

Address offset: 0x48

Reset value: 0x0000

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
	Reserved					DBL[4:0]					Reserved					DBA[4:0]				
						rw	rw	rw	rw	rw						rw	rw	rw	rw	rw

Bits 15:13 Reserved, always read as 0

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address).

- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ...
- 10001: 18 transfers.

Bits 7:5 Reserved, always read as 0

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

- 00000: TIMx\_CR1,
- 00001: TIMx\_CR2,
- 00010: TIMx\_SMCR,
- ...

**Example:** Let us consider the following transfer: DBL = 7 bytes & DBA = TIMx\_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx\_CR1 address..

– If DBL = 7 bytes and DBA = TIM2\_CR1 represents the address of the byte to be transferred, the address of the transfer should be given by the following equation:

$$(TIMx\_CR1 \text{ address}) + DBA + (DMA \text{ index}), \text{ where } DMA \text{ index} = DBL$$

In this example, 7 bytes are added to (TIMx\_CR1 address) + DBA, which gives us the address from/to which the data will be copied. In this case, the transfer is done to 7 registers starting from the following address: (TIMx\_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

– If you configure the DMA Data Size in half-words, 16-bit data will be transferred to each of the 7 registers.

If you configure the DMA Data Size in bytes, the data will also be transferred to 7 registers: the first register will contain the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, you also have to specify the size of data transferred by DMA.

### 13.4.18 TIMx DMA address for full transfer (TIMx\_DMAR)

Address offset: 0x4C

Reset value: 0x0000

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DMAB[15:0]															
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses

A read or write access to the DMAR register accesses the register located at the address:

“(TIMx\_CR1 address) + DBA + (DMA index)” in which:

TIMx\_CR1 address is the address of the control register 1,

DBA is the DMA base address configured in the TIMx\_DCR register,

DMA index is the offset automatically controlled by the DMA transfer, depending on the length of the transfer DBL in the TIMx\_DCR register.

#### Example of using the DMA burst feature:

In this example the Timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

- Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
- Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
DBL = 3 transfers, DBA = 0xE.
- Enable the TIMx update DMA request (set the UDE bit in the DIER register).
- Enable TIMx
- Enable the DMA channel

*Note: This example is for the case where every CCRx register to to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.*

### 13.4.19 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

**Table 55. TIM2 to TIM4 register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 14 General-purpose timers (TIM9/10/11)

### 14.1 TIM9/10/11 introduction

The TIM9, TIM10 and TIM11 general-purpose timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (*input capture*) or generating output waveforms (*output compare and PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM9, TIM10 and TIM11 timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 14.3.12](#).

### 14.2 TIM9/10/11 main features

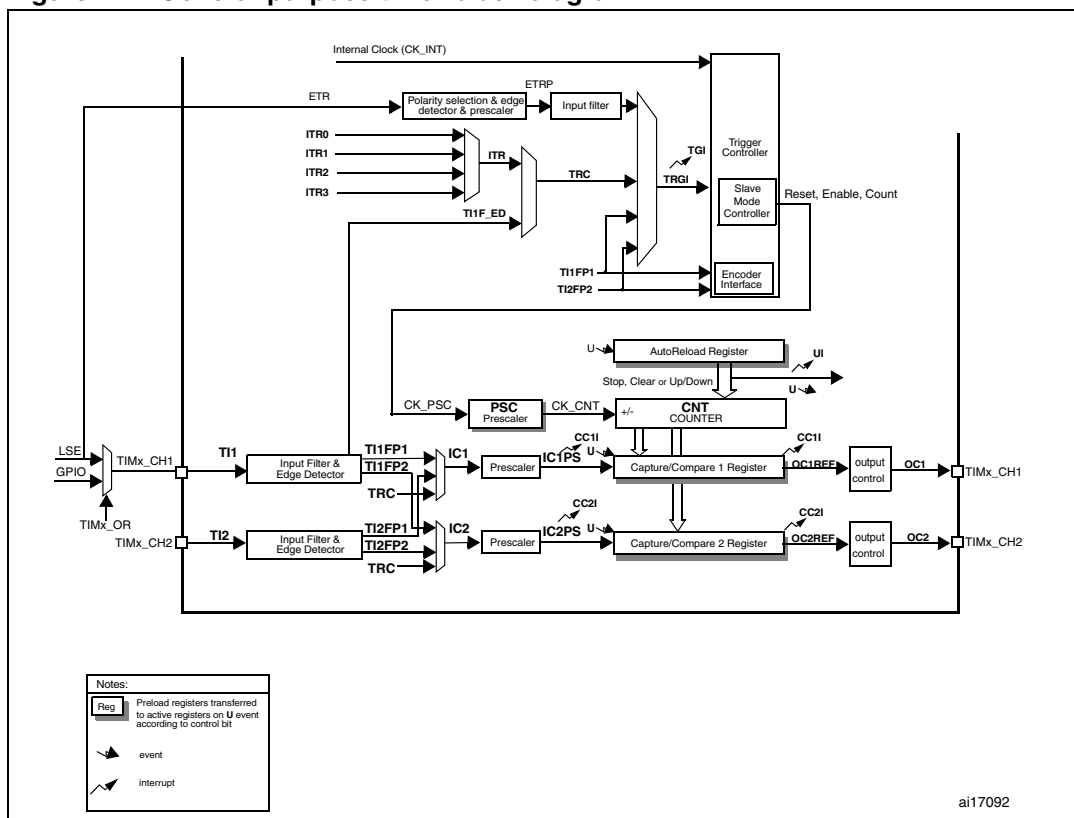

#### 14.2.1 TIM9 main features

The 2-channel TIM9 timer features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (including “on the fly”) the counter clock frequency by any factor between 1 and 65535
- 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals, and to interconnect several timers
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare
- Trigger input for external clock or cycle-by-cycle current management

Figure 112. General-purpose timer block diagram

### 14.2.2 TIM10 and TIM11 main features

The 1-channel TIM10 and TIM11 timer features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (including “on the fly”) the counter clock frequency by any factor between 1 and 65535
- 1 independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

Figure 113. General-purpose timer block diagram (TIM10)

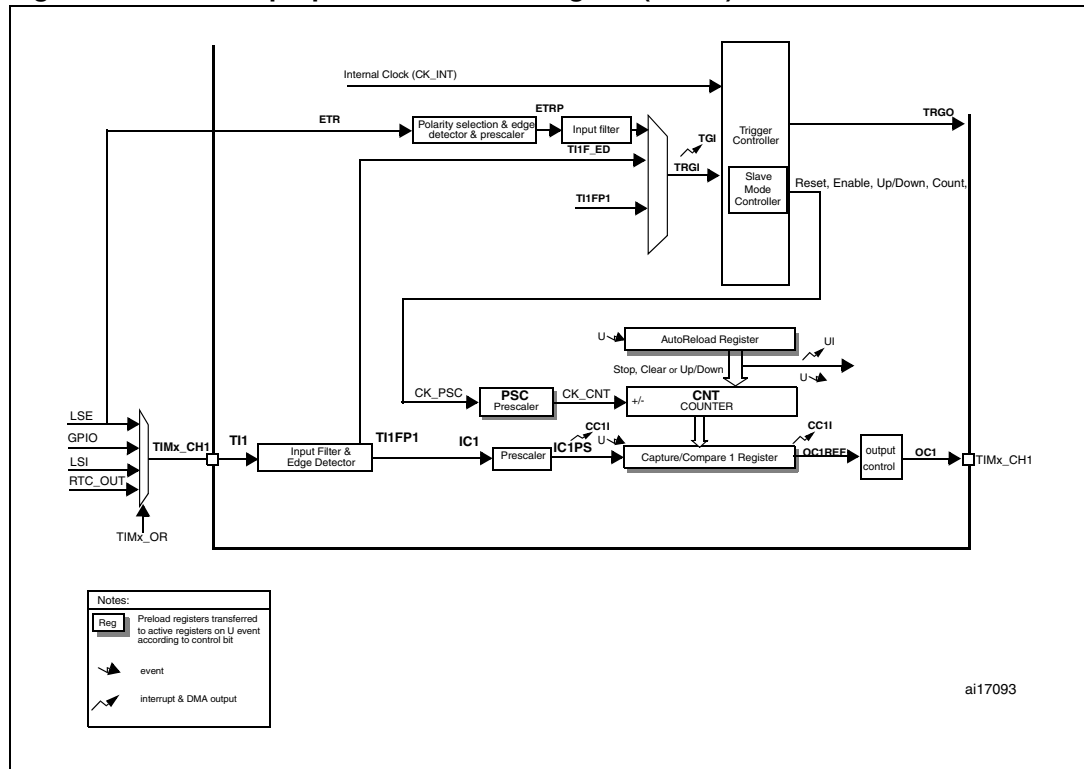

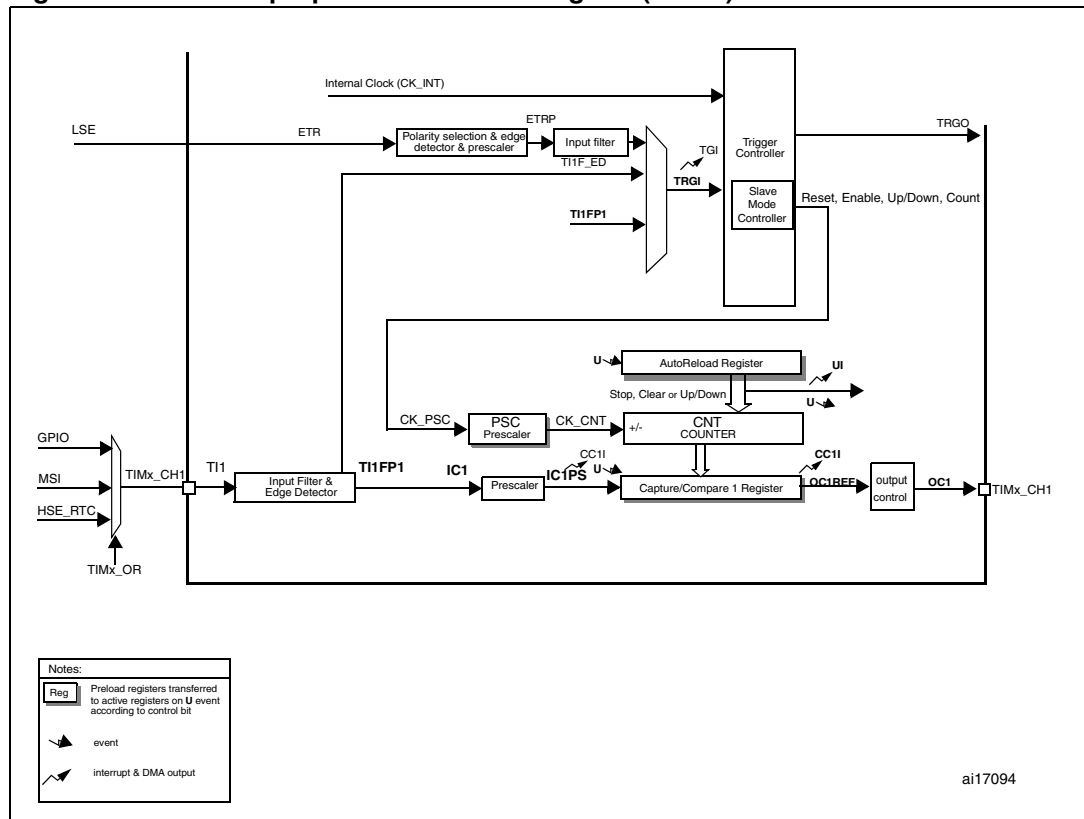

Figure 114. General-purpose timer block diagram (TIM11)

## 14.3 TIM9/10/11 functional description

### 14.3.1 Time-base unit

The main block of the programmable timer is a 16-bit counter with its related auto-reload register. The counter can count up only. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-reload register (TIMx\_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The contents of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in the TIMx\_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

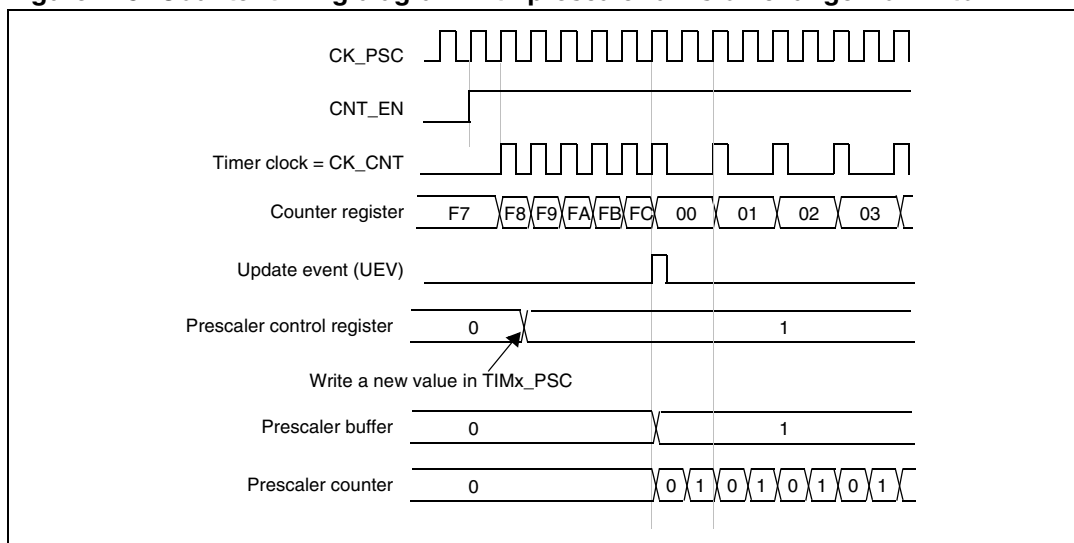

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

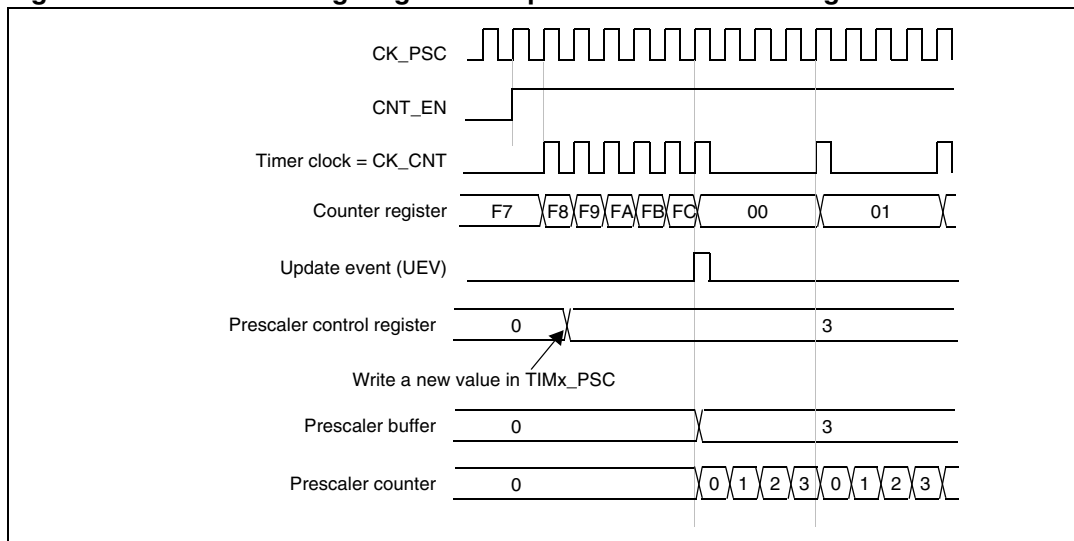

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 115* and *Figure 116* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

**Figure 115. Counter timing diagram with prescaler division change from 1 to 2**

**Figure 116. Counter timing diagram with prescaler division change from 1 to 4**

### 14.3.2 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values to the preload registers. Then no update event occurs until the UDIS bit is written to 0. The counter, however, restarts from 0, as well as the prescaler's counter (but the prescaler rate does not change). In addition, if the URS bit (update request selection) in the TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF

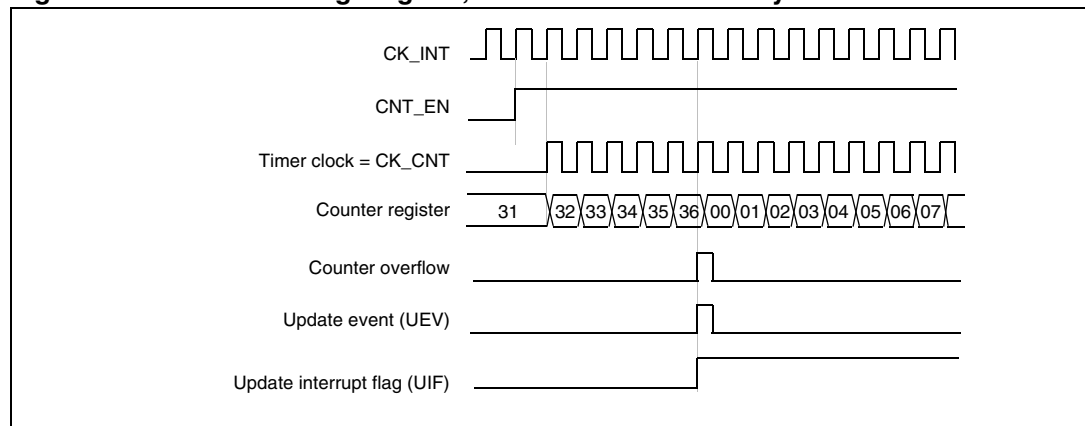

flag (thus no interrupt request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx\_SR register) is set (depending on the URS bit):

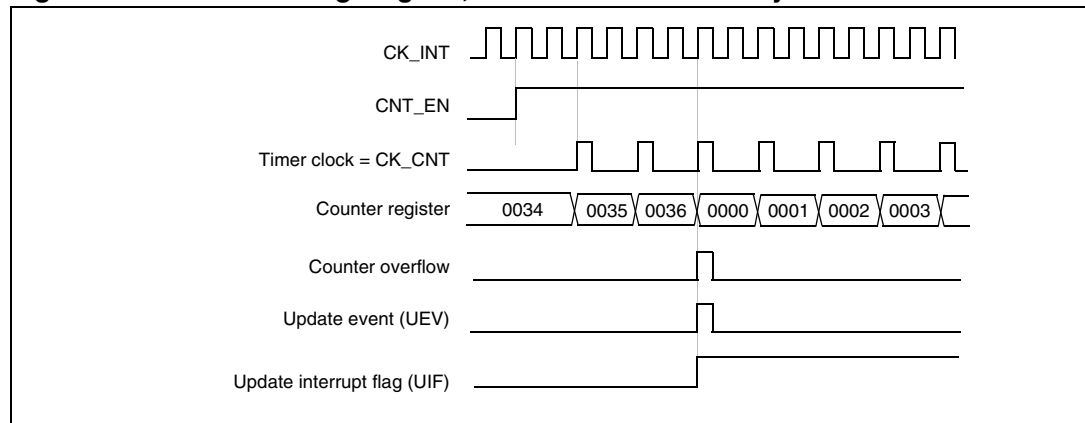

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

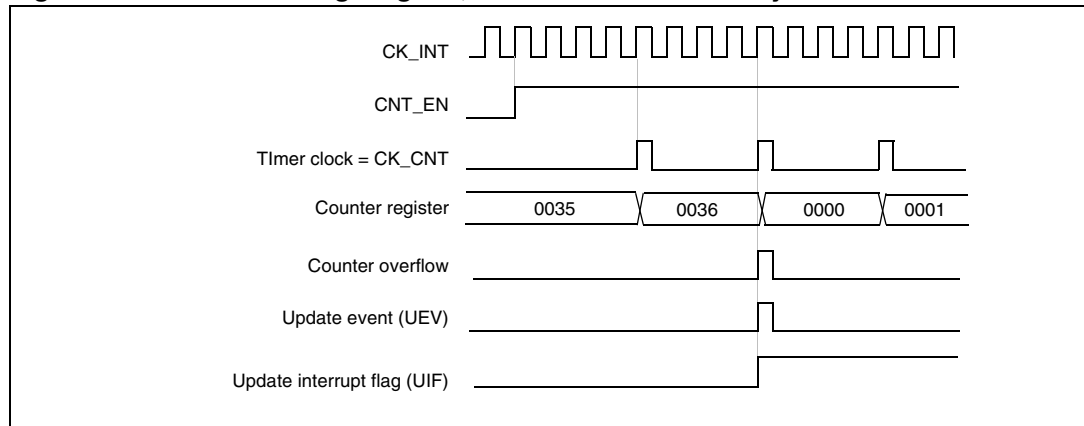

**Figure 117. Counter timing diagram, internal clock divided by 1**

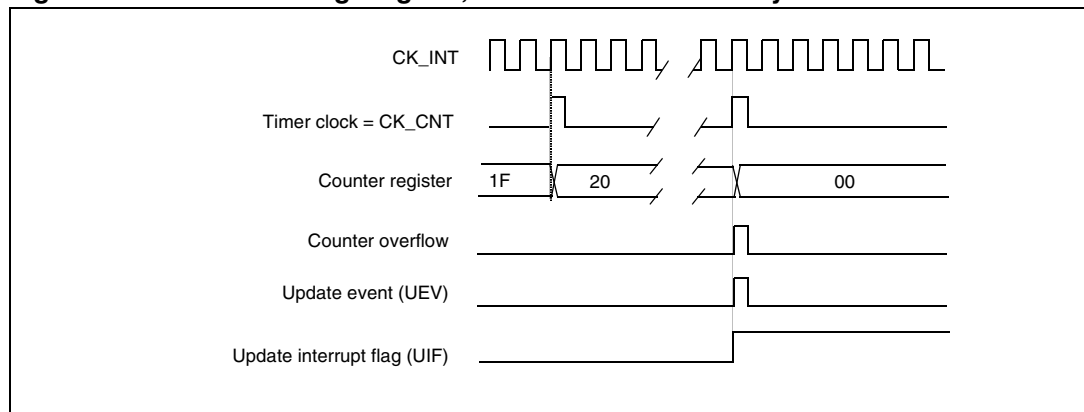

**Figure 118. Counter timing diagram, internal clock divided by 2**

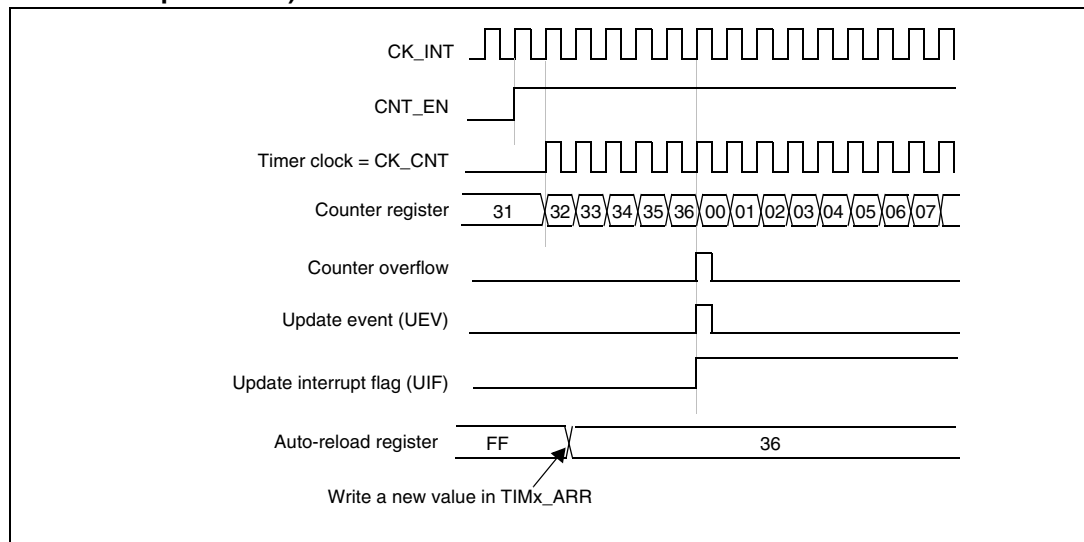

**Figure 119. Counter timing diagram, internal clock divided by 4**

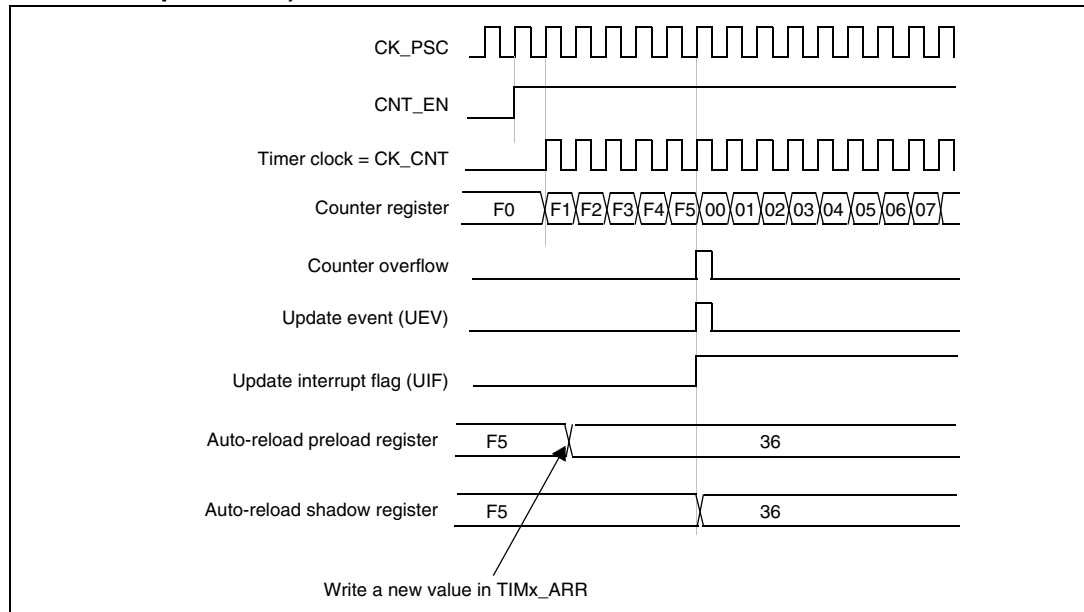

**Figure 120. Counter timing diagram, internal clock divided by N**

**Figure 121. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)**

**Figure 122. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

### 14.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as the prescaler for another timer, available for TIM9 only. For example, you can configure TIM9 to act as the prescaler for TIM2. Refer to [Using one timer as the prescaler for another](#) for more details.

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx\_SMCR register), then the CEN bit (in the TIMx\_CR1 register) and the UG bit (in the TIMx\_EGR register) are actual control bits. The CEN bit can be changed only by software while the UG bit remains cleared automatically. As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 123](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

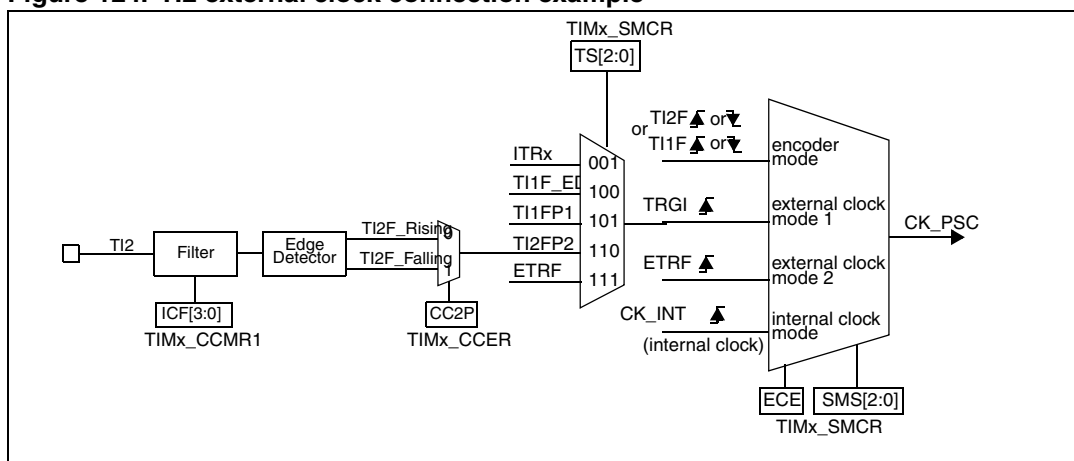

**Figure 123. Control circuit in normal mode, internal clock divided by 1**

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

**Figure 124. TI2 external clock connection example**

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S= 01 to the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).

*Note: The capture prescaler is not used for triggering, so you do not need to configure it.*

3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on the TI2 input.

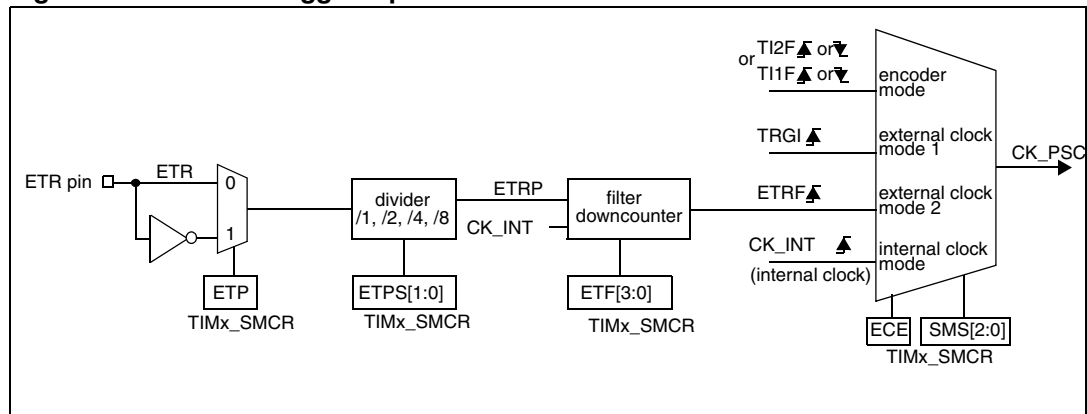

### External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

Figure 125 gives an overview of the external trigger input block.

Figure 125. External trigger input block

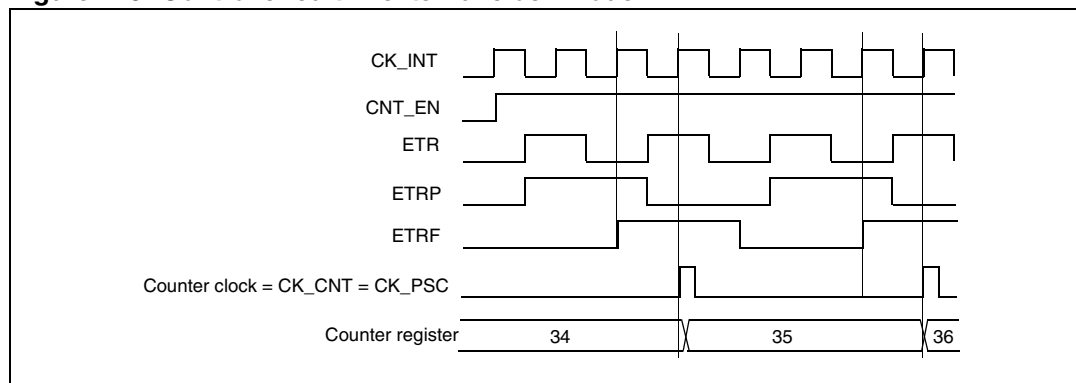

For example, to configure the upcounter to count every 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx\_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx\_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter counts once every 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

Figure 126. Control circuit in external clock mode 2

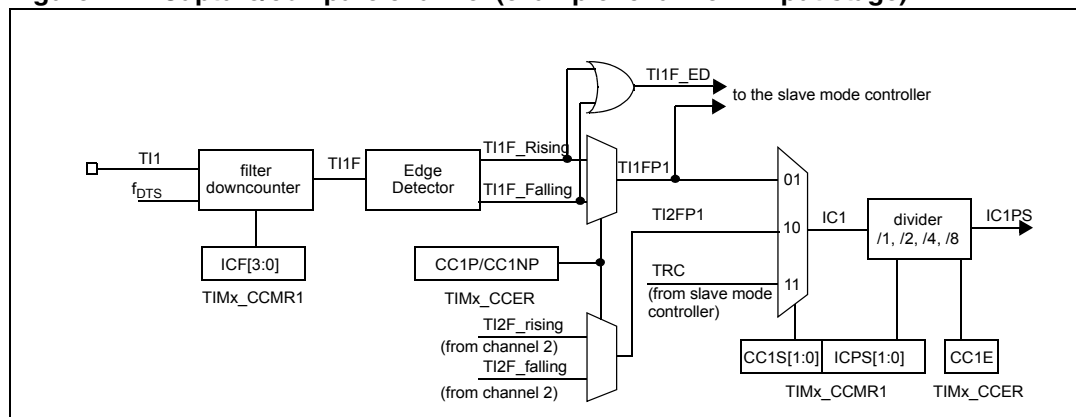

### 14.3.4 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of a capture/compare channel.

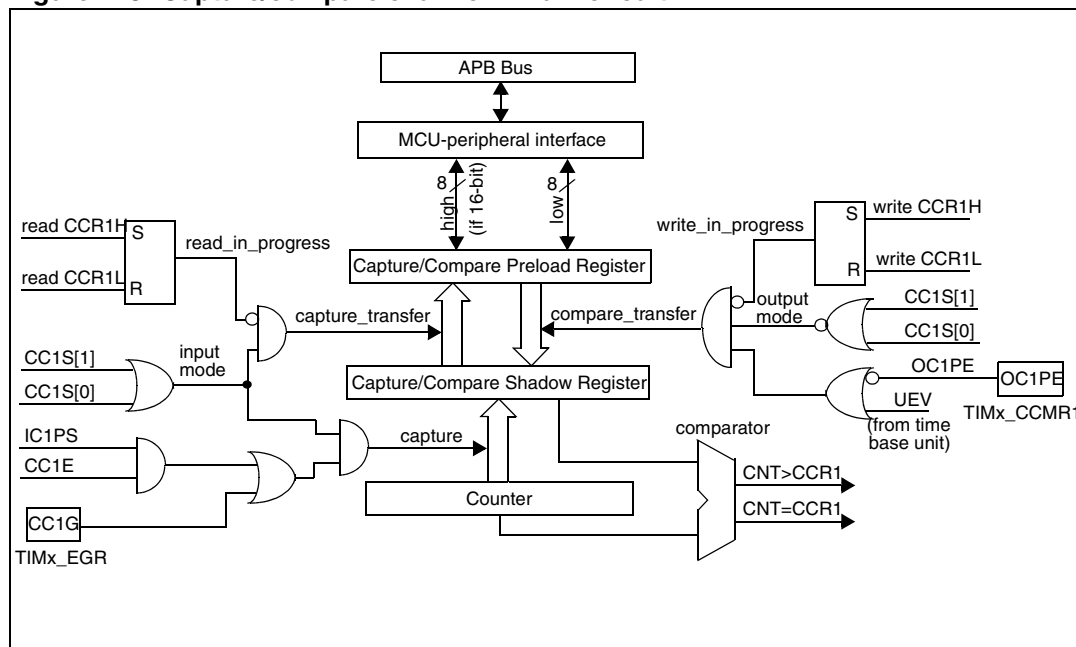

The input stage samples the corresponding Tix input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as the trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

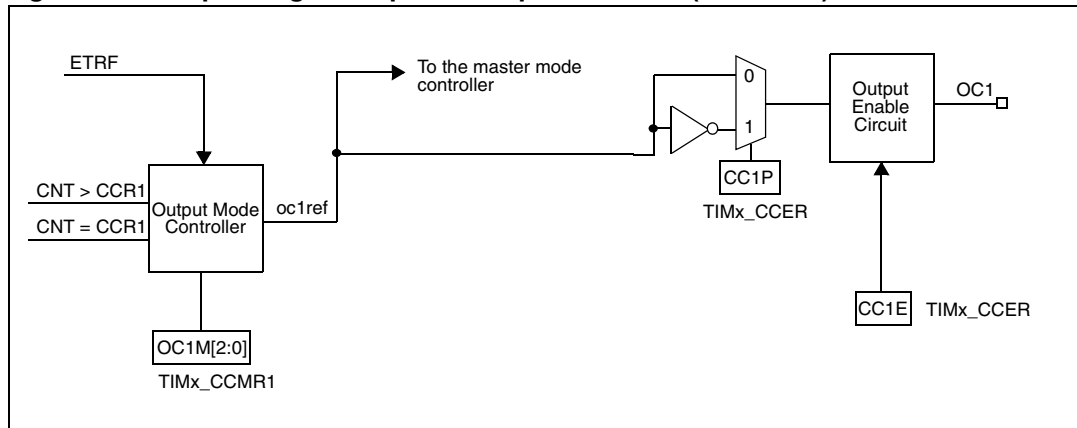

**Figure 127. Capture/compare channel (example: channel 1 input stage)**

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 128. Capture/compare channel 1 main circuit**

**Figure 129. Output stage of capture/compare channel (channel 1)**

The capture/compare block is made of a preload register and a shadow register. Write and read operations always access the preload register.

In capture mode, captures are actually made in the shadow register, and then copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 14.3.5 Input capture mode

In Input capture mode, the capture/compare registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx\_SR register) is set and an interrupt request can be sent if it is enabled. If a capture occurs while the CCxIF flag is already high, then the overcapture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when you write it to 0.

The following example shows how to capture the counter value in TIMx\_CCR1 when the TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input mode and the TIMx\_CCR1 register becomes read-only.
- Program the needed input filter duration with respect to the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx\_CCMRx register)). Let us imagine that, when toggling, the input signal is not stable for at most 5 internal clock cycles. We will need to program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write the IC1F bits to 0011 in the TIMx\_CCMR1 register.
- Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP bits to 00 in the TIMx\_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write the IC1PS bits to 00 in the TIMx\_CCMR1 register).

- Enable capture from the counter in the capture register by setting the CC1E bit in the TIMx\_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- The CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred while the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* An IC interrupt request can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 14.3.6 PWM input mode (available for TIM9 only)

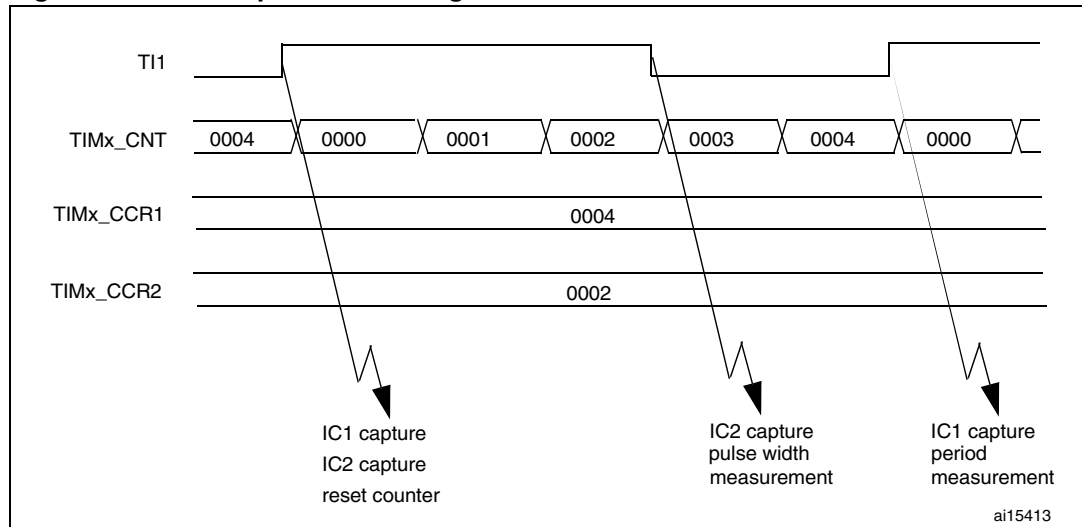

This mode is a particular case of the input capture mode. The procedure is the same except that:

- two ICx signals are mapped on the same TIx input
- these 2 ICx signals are active on edges with opposite polarity
- one of the two TIxFP signals is selected as the trigger input and the slave mode controller is configured in reset mode

For example, you can measure the period (in the TIMx\_CCR1 register) and the duty cycle (in the TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

- Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P and the CC1NP bits to 00 (active on rising edge).
- Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P bit to 1 and the CC2NP bit to 0 (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1 in the TIMx\_CCER register.

Figure 130. PWM input mode timing

### 14.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, you just need to write 101 to the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx gets the opposite value to the CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the Output compare mode section.

### 14.3.8 Output compare mode

This function is used to control an output waveform or to indicate when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx\_DIER register).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

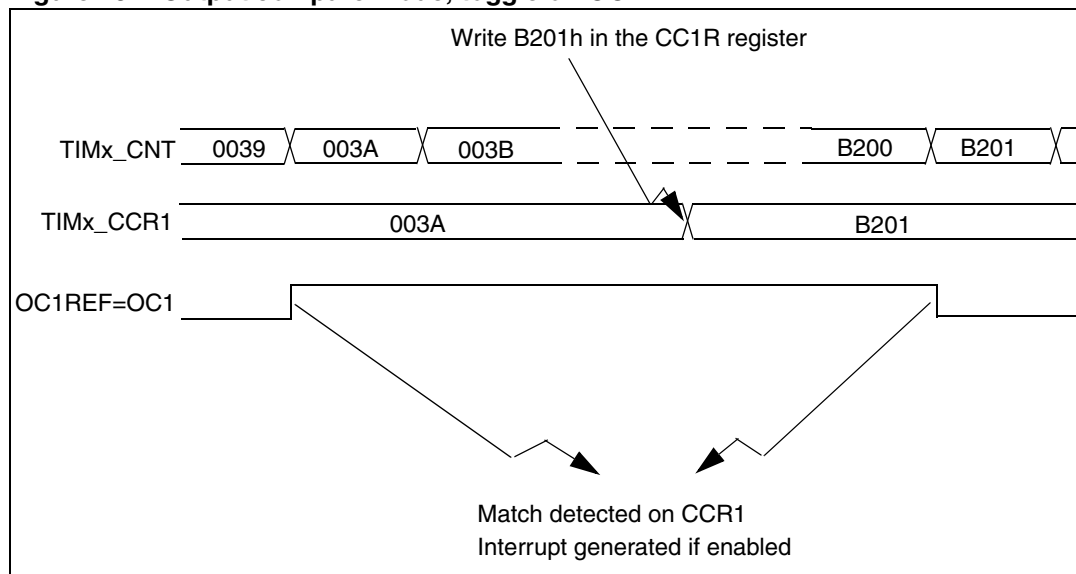

In output compare mode, the update event UEV has no effect on the OCxREF and OCx output. The timing resolution is one count of the counter. The output compare mode can also be used to output a single pulse (in one-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt request is to be generated.
4. Select the output mode. For example, you must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle the OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else the TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 131](#).

**Figure 131. Output compare mode, toggle on OC1**

### 14.3.9 PWM mode

The Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or 111 (PWM mode 2) to the OCxM bits in the TIMx\_CCMRx register. You must enable the corresponding preload register by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, you have to initialize all the registers by setting the UG bit in the TIMx\_EGR register.

The OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. The OCx output is enabled by the CCxE bit in the TIMx\_CCER register. Refer to the TIMx\_CCERx register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CNT \leq TIMx\_CCRx$ . However, to comply with the OCREF\_CLR functionality (OCREF can be cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- when the result of the comparison changes, or
- when the output compare mode (OCxM bits in the TIMx\_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=000) to one of the PWM modes (OCxM=110 or 111).

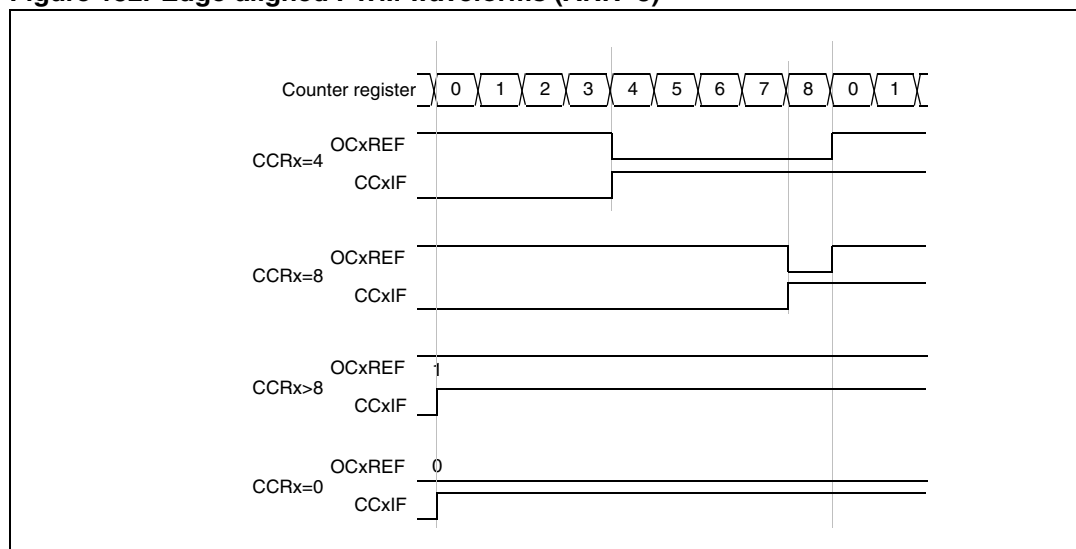

This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode only since the counter mode is upcounting.

### PWM edge-aligned mode

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at 1. If the compare value is 0 then OCxREF is held at 0. [Figure 132](#) shows some edge-aligned PWM waveforms in an example where  $TIMx\_ARR=8$ .

**Figure 132. Edge-aligned PWM waveforms (ARR=8)**

### 14.3.10 One-pulse mode (available for TIM9 only)

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus, and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. The waveform can be generated in output compare mode or PWM mode. You select One-pulse mode by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter's initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

$$CNT < CCRx \leq ARR \text{ (in particular, } 0 < CCRx)$$

**Figure 133. Example of one-pulse mode.**

For example you may want to generate a positive pulse on OC1 with a length of  $t_{PULSE}$  and after a delay of  $t_{DELAY}$  as soon as a positive edge is detected on the TI2 input pin.

Let us use TI2FP2 as trigger 1:

- Map TI2FP2 on TI2 by writing IC2S=01 in the TIMx\_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP=0 in the TIMx\_CCER register.
- Configure TI2FP2 as the trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx\_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to 110 in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- $t_{DELAY}$  is defined by the value written in the TIMx\_CCR1 register.
- $t_{PULSE}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).

- Let us say that you want to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the auto-reload value. To do this you enable PWM mode 2 by writing OC1M=111 in the TIMx\_CCMR1 register. You can optionally enable the preload registers by writing OC1PE=1 in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case you have to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for an external trigger event on TI2. CC1P is written to 0 in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

You only want 1 pulse, so you write 1 to the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

#### Particular case: OCx fast enable

In One-pulse mode, edge detection on the Tix input sets the CEN bit, which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and, limiting the minimum delay  $t_{DELAY}$  we can get.

If you want to output a waveform with the minimum delay, you can set the OCxFE bit in the TIMx\_CCMRx register. Then OCxREF (and OCx) is forced in response to the stimulus, without taking the comparison into account. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 14.3.11 Timers and external trigger synchronization (available for TIM9 only)

The TIM9/10/11 timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

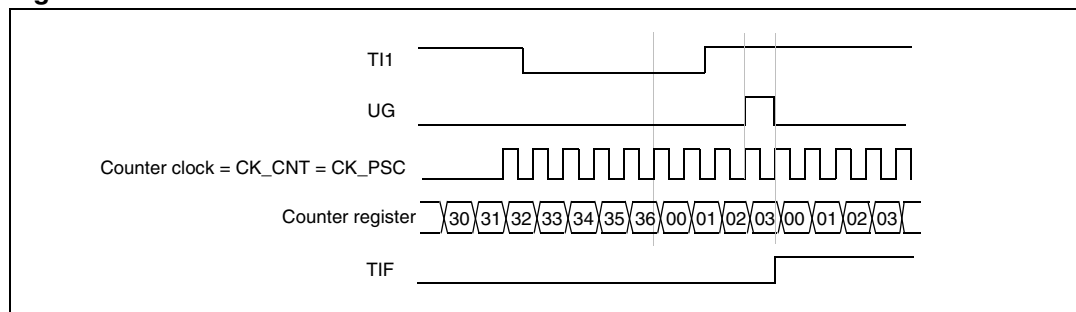

In the following example, the upcounter is cleared in response to a rising edge on the TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you do not need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P=0 and CC1NP=0 in the TIMx\_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in Reset mode by writing SMS=100 in the TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in the TIMx\_SMCR register.
- Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1's rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE bit in the TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on the TI1 input.

**Figure 134. Control circuit in Reset mode**

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

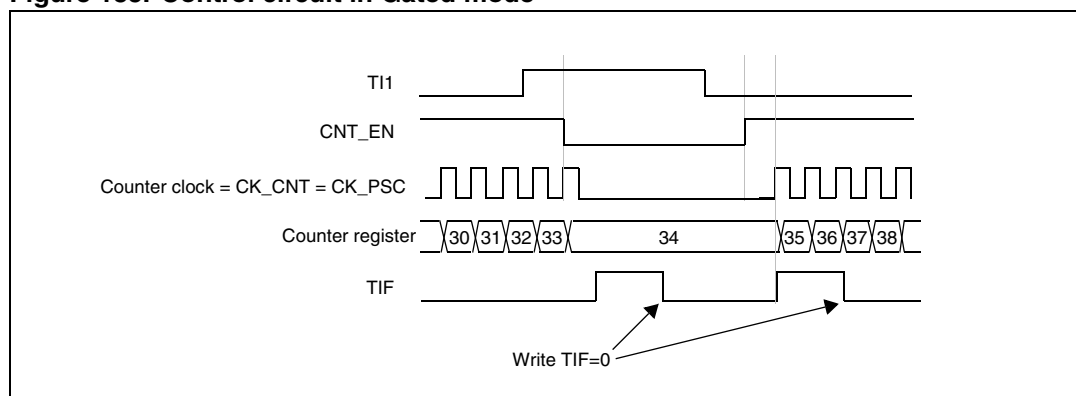

In the following example, the upcounter counts only when the TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so you do not need to configure it. The CC1S bits select the input capture source only, CC1S=01 in the TIMx\_CCMR1 register. Write CC1P=1 and CC1NP=0 in the TIMx\_CCER register to validate the polarity (and detect low levels only).
- Configure the timer in Gated mode by writing SMS=101 in the TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in the TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in Gated mode, the counter does not start if CEN=0, whatever the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on the TI1 input.

**Figure 135. Control circuit in Gated mode**

*Note:* The  $CCxP=CCxNP=1$  configuration (detection of both rising and falling edges) does not have any effect in the Gated mode because the Gated mode acts on levels and not on edges.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on the TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep  $IC2F=0000$ ). The capture prescaler is not used for triggering, so you do not need to configure it. The CC2S bits select the input capture source only,  $CC2S=01$  in the TIMx\_CCMR1 register. Write  $CC2P=1$  and  $CC2NP=0$  in the TIMx\_CCER register to validate the polarity (and detect low levels only).
- Configure the timer in Trigger mode by writing  $SMS=110$  in the TIMx\_SMCR register. Select TI2 as the input source by writing  $TS=110$  in the TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on the TI2 input.

**Figure 136. Control circuit in Trigger mode**

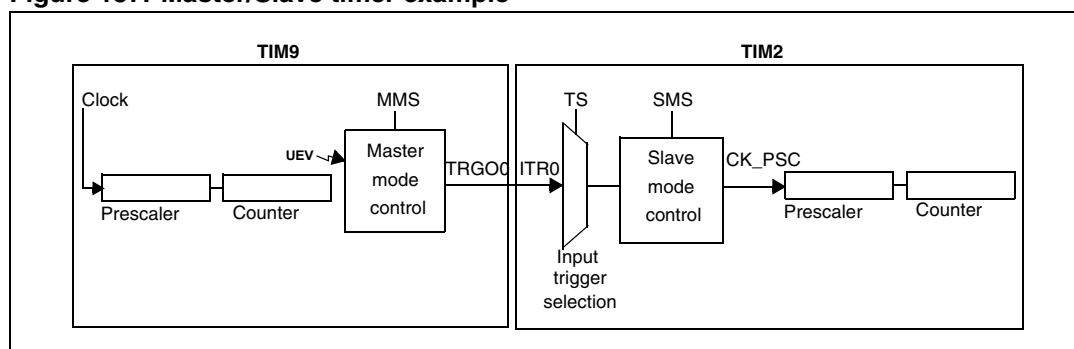

**14.3.12 Timer synchronization (available for TIM9 only)**

The timers are linked together internally for timer synchronization or chaining. When one timer is configured in Master mode, it can reset, start, stop or clock the counter of another timer configured in Slave mode.

The following figure presents an overview of the trigger selection and the Master mode selection blocks.

## Using one timer as the prescaler for another

**Figure 137. Master/Slave timer example**

For example, you can configure TIM9 to act as a prescaler for TIM2. Refer to [Figure 137](#). To do this:

- Configure TIM9 in Master mode so that it outputs a periodic trigger signal on each update event UEV. If you write MMS=010 in the TIM9\_CR2 register, a rising edge is output on TRGO0 each time an update event is generated.
- To connect the TRGO0 output of TIM9 to TIM2, TIM2 must be configured in Slave mode using ITR0 as the internal trigger. You select this through the TS bits in the TIM2\_SMCR register (writing TS=000).
- Then you put the slave mode controller in external clock mode 1 (write SMS=111 in the TIM2\_SMCR register). This causes TIM2 to be clocked by the rising edge of TIM9's periodic trigger signal (which corresponds to TIM9's counter overflow).
- Finally both timers must be enabled by setting their respective CEN bits (TIMx\_CR1 register).

*Note:* If OCx is selected on TIM9 as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM2.

## Using one timer to enable another timer

In this example, we use the output compare 1 of TIM9 to enable TIM2. Refer to [Figure 137](#) for connections. TIM2 counts on the divided internal clock only when the OC1REF of TIM9 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- Configure TIM9 in Master mode to send its output compare 1 reference (OC1REF) signal as the trigger output (MMS=100 in the TIM9\_CR2 register).
- Configure the TIM9's OC1REF waveform (TIM9\_CCMR1 register).
- Configure TIM2 to get the input trigger from TIM9 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in Gated mode (SMS=101 in the TIM2\_SMCR register).
- Enable TIM2 by writing 1 to the CEN bit (TIM2\_CR1 register).
- Start TIM9 by writing 1 to the CEN bit (TIM9\_CR1 register).

*Note:* The TIM2 counter clock is not synchronized with the TIM9 counter clock, this mode only affects the TIM2 counter enable signal.

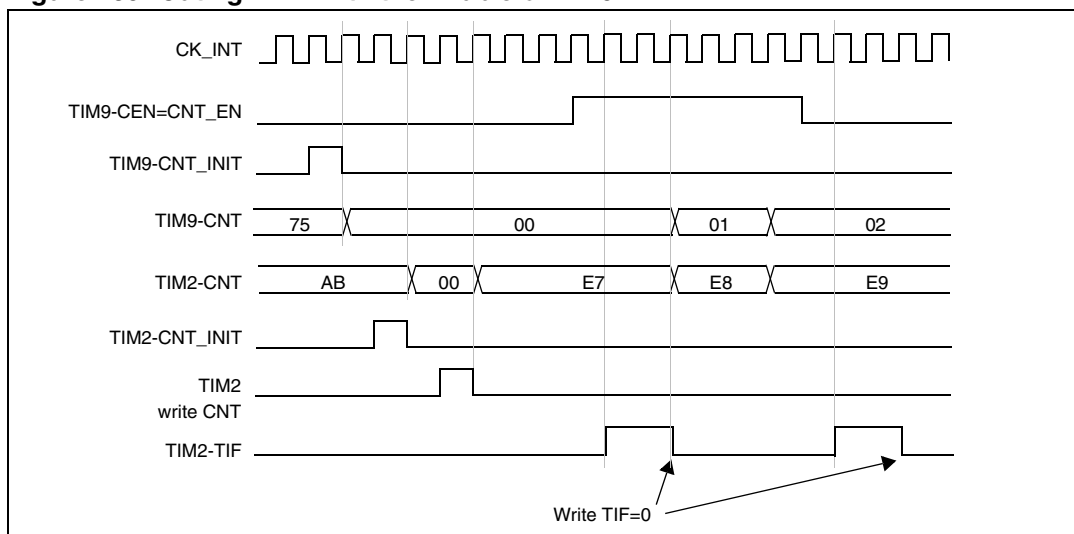

**Figure 138. Gating TIM2 with the OC1REF of TIM9**

In the example in [Figure 138](#), the TIM2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM9. You can then write any value into the timer counters. The timers can easily be reset by software using the UG bit in the TIMx\_EGR registers.

In the next example, we synchronize TIM9 and TIM2. TIM9 is the master and starts from 0. TIM2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM2 stops when TIM9 is disabled by writing 0 to the CEN bit in the TIM9\_CR1 register:

- Configure TIM9 in Master mode to send its output compare 1 reference (OC1REF) signal as the trigger output (MMS=100 in the TIM9\_CR2 register).
- Configure TIM9's OC1REF waveform (TIM9\_CCMR1 register).
- Configure TIM2 to get the input trigger from TIM9 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in Gated mode (SMS=101 in TIM2\_SMCR register).
- Reset TIM9 by writing 1 to the UG bit (TIM9\_EGR register).
- Reset TIM2 by writing 1 to the UG bit (TIM2\_EGR register).
- Initialize TIM2 to 0xE7 by writing 0xE7 to the TIM2 counter (TIM2\_CNT).
- Enable TIM2 by writing 1 to the CEN bit (TIM2\_CR1 register).
- Start TIM9 by writing 1 to the CEN bit (TIM9\_CR1 register).
- Stop TIM9 by writing 0 to the CEN bit (TIM9\_CR1 register).

**Figure 139. Gating TIM2 with the Enable of TIM9**

**Using one timer to start another timer**

In this example, we set the enable of TIM2 with the update event of TIM9. Refer to [Figure 137](#) for connections. TIM2 starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by TIM9. When TIM2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write 0 to the CEN bit in the TIM2\_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- Configure TIM9 in Master mode to send its update event (UEV) as the trigger output (MMS=010 in the TIM9\_CR2 register).
- Configure the TIM9 period (TIM9\_ARR registers).
- Configure TIM2 to get the input trigger from TIM9 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in Trigger mode (SMS=110 in TIM2\_SMCR register).
- Start TIM9 by writing 1 to the CEN bit (TIM9\_CR1 register).

**Figure 140. Triggering TIM2 with the update of TIM9**

As in the previous example, you can initialize both counters before starting counting. [Figure 141](#) shows the behavior with the same configuration as in [Figure 140](#) but in Trigger mode instead of Gated mode (SMS=110 in the TIM2\_SMCR register).

**Figure 141. Triggering TIM2 with the Enable of TIM9**

### Using one timer as the prescaler for another timer

For example, you can configure TIM9 to act as a prescaler for TIM2. Refer to [Figure 137](#) for connections. To do this:

- Configure TIM9 in Master mode to send its update event (UEV) as the trigger output (MMS=010 in the TIM9\_CR2 register). It then outputs a periodic signal on each counter overflow.
- Configure the TIM9 period (TIM9\_ARR registers).
- Configure TIM2 to get the input trigger from TIM9 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in external clock mode 1 (SMS=111 in TIM2\_SMCR register).
- Start TIM2 by writing 1 to the CEN bit (TIM2\_CR1 register).
- Start TIM9 by writing 1 to the CEN bit (TIM9\_CR1 register).

### Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM9 when its TI1 input rises, and the enable of TIM2 with the enable of TIM9. Refer to [Figure 137](#) for connections. To ensure that the counters

are aligned, TIM9 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to TIM2):

- Configure TIM9 in Master mode to send its Enable as the trigger output (MMS=001 in the TIM9\_CR2 register).
- Configure TIM9 in Slave mode to get the input trigger from TI1 (TS=100 in the TIM9\_SMCR register).
- Configure TIM9 in Trigger mode (SMS=110 in the TIM9\_SMCR register).
- Configure TIM9 in Master/Slave mode by writing MSM=1 (TIM9\_SMCR register).
- Configure TIM2 to get the input trigger from TIM9 (TS=000 in the TIM2\_SMCR register).
- Configure TIM2 in Trigger mode (SMS=110 in the TIM2\_SMCR register).

When a rising edge occurs on TI1 (TIM9), both counters starts counting synchronously on the internal clock and both TIF flags are set.

*Note:* In this example both timers are initialized before starting (by setting their respective UG bits). Both counters start from 0, but you can easily insert an offset between them by writing any of the counter registers (TIMx\_CNT). You can see that the master/slave mode inserts a delay between CNT\_EN and CK\_PSC on TIM9.

**Figure 142. Triggering TIM9 and TIM2 with TIM9's TI1 input.**

### 14.3.13 Debug mode

When the microcontroller enters the debug mode (Cortex-M3 core halted), the TIM9/10/11 counter either continues to work normally or stops, depending on the DBG\_TIMx\_STOP configuration bit in the DBGMCU module. For more details, refer to [Section 24.16.1: Debug support for low-power modes](#).

## 14.4 TIM9/10/11 registers

Refer to [Section 1.1](#) for a list of abbreviations used in register descriptions.

### 14.4.1 TIMx control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved						CKD[1:0]		ARPE	Reserved			res	OPM	URS	UDIS	CEN
						rw	rw	rw				rw	rw	rw	rw	rw

Bits 15:10 Reserved, always read as 0

Bits 9:8 **CKD**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (TIx),

- 00:  $t_{DTS} = t_{CK\_INT}$
- 01:  $t_{DTS} = 2 \times t_{CK\_INT}$
- 10:  $t_{DTS} = 4 \times t_{CK\_INT}$
- 11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

- 0: TIMx\_ARR register is not buffered.
- 1: TIMx\_ARR register is buffered.

Bits 6:4 Reserved

Bit 3 **OPM**: One-pulse mode

- 0: Counter is not stopped on the update event
- 1: Counter stops counting on the next update event (clearing the CEN bit).

*Note: This bit is not available for the TIM10/11 timers.*

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled. These events are:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable the update event (UEV) generation.

0: UEV enabled. The UEV event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The UEV is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable  
 0: Counter disabled  
 1: Counter enabled

CEN is cleared automatically in one-pulse mode, when an update event occurs.

### 14.4.2 TIMx control register 2 (TIMx\_CR2) (available for TIM9 only)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Res.	MMS[2:0]			Res.	Reserved			
								rw	rw	rw					

Bits 15:7 Reserved, always read as 0.

Bits 6:4 **MMS**: Master mode selection

These bits are used to select the information to be sent in Master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit in the TIMx\_EGR register is used as the trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as the trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between the CEN control bit and the trigger input when configured in Gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in the TIMx\_SMCR register).

010: **Update** - The update event is selected as the trigger output (TRGO). For instance a master timer can be used as a prescaler for a slave timer.

011: **Compare pulse** - The trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurs. (TRGO).

100: **Compare** - OC1REF signal is used as the trigger output (TRGO).

101: **Compare** - OC2REF signal is used as the trigger output (TRGO).

110: Reserved

111: Reserved

Bits 3:0 Reserved, always read as 0.

### 14.4.3 TIMx slave mode control register (TIMx\_SMCR)

Address offset: 0x08

Reset value: 0x0000

#### TIM9\_SMCR

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS[1:0]		ETF[3:0]				MSM	TS[2:0]			Res.	SMS[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw

#### TIM10/11\_SMCR

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
ETP	ECE	ETPS[1:0]		ETF[3:0]				Reserved								
rw	rw	rw	rw	rw	rw	rw	rw									

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{ETR}$  is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge

1: ETR is inverted, active at low level or falling edge

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal

*Note: 1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).*

*2: It is possible to simultaneously use external clock mode 2 with the following slave modes: Reset mode, Gated mode and Trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must **not** be 111).*

*3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.*

Bits 13:12 **ETPS**: External trigger prescaler

The frequency of the external trigger signal ETRP must be at most 1/4 of the CK\_INT frequency. A prescaler can be enabled to reduce the ETRP frequency. It is useful when inputting fast external clocks.

00: Prescaler OFF.

01: ETRP frequency divided by 2

10: ETRP frequency divided by 4

11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bitfield then defines the frequency used to sample the ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bit 7<sup>(1)</sup> **MSM**: Master/Slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful in order to synchronize several timers on a single external event.

Bits 6:4<sup>(1)</sup> **TS**: Trigger selection

This bitfield selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0)

001: Internal Trigger 1 (ITR1)

010: Internal Trigger 2 (ITR2)

011: Internal Trigger 3 (ITR3)

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

111: Reserved.

See [Table 56: TIMx internal trigger connection on page 357](#) for more details on the meaning of ITRx for each timer.

*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

Bit 3<sup>(1)</sup> Reserved, always read as 0.

Bits 2:0<sup>(1)</sup> **SMS**: Slave mode selection

When external signals are selected, the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input control register and Control register descriptions).

000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock

001: Reserved

010: Reserved

011: Reserved

100: Reset mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers

101: Gated mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Counter starts and stops are both controlled

110: Trigger mode - The counter starts on a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled

111: External clock mode 1 - Rising edges of the selected trigger (TRGI) clock the counter

*Note: The Gated mode must not be used if TI1F\_ED is selected as the trigger input (TS=100). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the Gated mode checks the level of the trigger signal.*

1. Bits [7:0] are not available for TIM10 and TIM11.

**Table 56. TIMx internal trigger connection**

Slave TIM	ITR0 (TS = 000)	ITR1 (TS = 001)	ITR2 (TS = 010)	ITR3 (TS = 011)
TIM9	TIM2	TIM3	TIM10	TIM11

### 14.4.4 TIMx Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									TIE	Res			CC2IE	CC1IE	UIE
									rw				rw	rw	rw

Bit 15:7 Reserved, always read as 0.

Bit 6 **TIE**: Trigger interrupt enable  
 0: Trigger interrupt disabled  
 1: Trigger interrupt enabled

*Note: This bit is not available for the TIM10/11 timers.*

Bit 5:3 Reserved, always read as 0.

Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable  
 0: CC2 interrupt disabled  
 1: CC2 interrupt enabled

*Note: This bit is not available for the TIM10/11 timers.*

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable  
 0: CC1 interrupt disabled  
 1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable  
 0: Update interrupt disabled  
 1: Update interrupt enabled

### 14.4.5 TIMx status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				CC2OF	CC1OF	Reserved			TIF	Reserved			CC2IF	CC1IF	UIF
				rc_w0	rc_w0				rc_w0				rc_w0	rc_w0	rc_w0

Bit 15:11 Reserved, always read as 0.

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag  
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.  
 0: No overcapture has been detected  
 1: The counter value was captured in the TIMx\_CCR1 register with the CC1IF flag already set

*Note: This bit is not available for the TIM10/11 timers.*

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.  
 0: No overcapture has been detected  
 1: The counter value was captured in the TIMx\_CCR1 register with the CC1IF flag already set

Bits 8:7 Reserved, always read as 0.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on a trigger event (active edge detected on the TRGI input when the slave mode controller is enabled in all modes except for the Gated mode. It is set when the counter starts or stops and the Gated mode is selected. It is cleared by software.

0: No trigger event occurred

1: Trigger interrupt pending

*Note: This bit is not available for the TIM10/11 timers.*

Bit 5:3 Reserved, always read as 0

Bit 2 **CC2IF**: Capture/compare 2 interrupt flag

**If channel CC2 is configured as output:**

This flag is set by hardware when the counter matches the compare value, with some exception in the center-aligned mode (refer to the CMS bits in the TIMx\_CR1 register description). It is cleared by software.

0: No match

1: The contents of the TIMx\_CNT counter match the contents of the TIMx\_CCR1 register.

When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC2IF bit goes high on the counter overflow (in upcounting and up/downcounting modes) or underflow (in downcounting mode)

**If channel CC2 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred

1: The counter value has been captured in the TIMx\_CCR1 register (an edge has been detected on IC1 that matches the selected polarity)

*Note: This bit is not available for the TIM10/11 timers.*

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

**If channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value, with some exception in the center-aligned mode (refer to the CMS bits in the TIMx\_CR1 register description). It is cleared by software.

0: No match

1: The contents of the TIMx\_CNT counter match the contents of the TIMx\_CCR1 register.

When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/downcounting modes) or underflow (in downcounting mode)

**If channel CC1 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred

1: The counter value has been captured in the TIMx\_CCR1 register (an edge has been detected on IC1 that matches the selected polarity)

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- on overflow and if UDIS=0 in the TIMx\_CR1 register
- when CNT is reinitialized by software using the UG bit in the TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register
- when CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

### 14.4.6 TIMx event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									TG	Reserved			CC2G	CC1G	UG
									w				w	w	w

Bits 15:7 Reserved, always read as 0.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in the TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled

*Note: This bit is not available for the TIM10/11 timers.*

Bits 5:3 Reserved, always read as 0.

Bit 2 **CC2G**: Capture/compare 2 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC2 is configured as output:**

the CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled.

**If channel CC2 is configured as input:**

The current counter value is captured in the TIMx\_CCR1 register. The CC2IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC2OF flag is set if the CC2IF flag was already high.

*Note: This bit is not available on the TIM10/TIM11 timers.*

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

the CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current counter value is captured in the TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initializes the counter and generates an update of the registers. Note that the prescaler counter is cleared too (the prescaler ratio is not affected). The counter is cleared if DIR=0 (upcounting)

### 14.4.7 TIMx capture/compare mode register 1 (TIMx\_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes. For a given bit, OCxx describes its function when the channel is configured in output mode, ICxx describes its function when the channel is configured in input mode. So you must take care that the same bit can have different meanings for the input stage and the output stage.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OC2 CE	OC2M[2:0]			OC2 PE	OC2 FE	CC2S[1:0]		OC1 CE	OC1M[2:0]			OC1 PE	OC1 FE	CC1S[1:0]	
IC2F[3:0]				IC2PSC[1:0]				IC1F[3:0]				IC1PSC[1:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

#### Output compare mode

Bit 15 **OC2CE**: Output compare 2 clear enable  
*Note: This bit is not available for the TIM10/11 timers.*

Bits 14:12 *Note: **OC2M[2:0]**: Output compare 2 mode*  
*Note: This bit is not available for the TIM10/11 timers.*

Bit 11 *Note: **OC2PE**: Output compare 2 preload enable*  
*Note: This bit is not available for the TIM10/11 timers.*

Bit 10 *Note: **OC2FE**: Output compare 2 fast enable*  
*Note: This bit is not available for the TIM10/11 timers.*

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection  
 This bitfield defines the direction of the channel (input/output) as well as the used input.  
 00: CC2 channel is configured as output  
 01: CC2 channel is configured as input, IC2 is mapped on TI2  
 10: CC2 channel is configured as input, IC2 is mapped on TI1  
 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)  
*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER). This bit is not available for the TIM10/11 timers.*

Bit 7 **OC1CE**: Output compare 1 clear enable  
 OC1CE: Output compare 1 clear enable  
 0: OC1REF is not affected by the ETRF input  
 1: OC1REF is cleared as soon as a high level is detected on the ETRF input

Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas the active levels of OC1 and OC1N depend on the CC1P and CC1NP bits, respectively.

000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs

001: Set channel 1 to active level on match. The OC1REF signal is forced high when the TIMx\_CNT counter matches the capture/compare register 1 (TIMx\_CCR1).

010: Set channel 1 to inactive level on match. The OC1REF signal is forced low when the TIMx\_CNT counter matches the capture/compare register 1 (TIMx\_CCR1).

011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1

100: Force inactive level - OC1REF is forced low

101: Force active level - OC1REF is forced high

110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else it is inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx\_CNT>TIMx\_CCR1, else it is active (OC1REF=1)

111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else it is active. In downcounting, channel 1 is active as long as TIMx\_CNT>TIMx\_CCR1 else it is inactive.

*Note: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken into account immediately

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded into the active register at each update event

*Note: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in the TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.  
0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles

1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bits 7:4 **IC1F**: Input capture 1 filter

This bitfield defines the frequency used to sample the TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2.

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

*Note: In the current silicon revision,  $f_{DTS}$  is replaced in the formula by  $CK\_INT$  when  $ICx[3:0]=1, 2$  or  $3$ .*

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on the CC1 input (IC1).

The prescaler is reset as soon as  $CC1E=0$  (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

### 14.4.8 TIMx capture/compare enable register (TIMx\_CCER)

Address offset: 0x20

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								CC2NP	Res.	CC2P	CC2E	CC1NP	Res.	CC1P	CC1E
								rw		rw	rw	rw		rw	rw

Bit 15:8 Reserved

Bit 7 **CC2NP**: Capture/Compare 2 output polarity

Note: Refer to the CC1NP description.

This bit is not available for the TIM10/11 timers.

Bit 6 Reserved, always read as 0.

Bit 5 **CC2P**: Capture/Compare 2 output polarity

Note: Refer to the CC1P description.

This bit is not available for the TIM10/11 timers.

Bit 4 **CC2E**: Capture/Compare 2 output enable

Note: Refer to the CC1E description.

This bit is not available for the TIM10/11 timers.

Bit 3 **CC1NP**: Capture/Compare 1 output polarity

**CC1 channel configured as output:**

CC1NP must be kept cleared in this case.

**CC1 channel configured as input:**

This bit is used in conjunction with CC1P to define the TI1FP1/TI2FP1 polarity. refer to the CC1P description.

Bit 2 Reserved, always read as 0.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

**CC1 channel configured as output:**

0: OC1 active high

1: OC1 active low

**CC1 channel configured as input:**

The CC1NP/CC1P bits select the polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

00: noninverted/rising edge: circuit is sensitive to TlxFP1's rising edge (capture, trigger in reset, external clock or trigger mode), TlxFP1 is not inverted (trigger in gated mode, encoder mode).

01: inverted/falling edge: circuit is sensitive to TlxFP1's falling edge (capture, trigger in reset, external clock or trigger mode), TlxFP1 is inverted (trigger in gated mode, encoder mode).

10: reserved, do not use this configuration.

11: noninverted/both edges: circuit is sensitive to both the rising and falling edges of TlxFP1 (capture, trigger in reset, external clock or trigger mode), TlxFP1 is not inverted (trigger in gated mode). This configuration must not be used for the encoder mode.

Bit 0 **CC1E**: Capture/Compare 1 output enable

**CC1 channel configured as output:**

0: Off - OC1 is not active

1: On - OC1 signal is output on the corresponding output pin

**CC1 channel configured as input:**

This bit determines if a capture of the counter value can be done into the input capture/compare register 1 (TIMx\_CCR1) or not

0: Capture disabled

1: Capture enabled

**Table 57. Output control bit for standard OCx channels**

CCxE bit	OCx output state
0	Output disabled (OCx=0, OCx_EN=0)
1	OCx=OCxREF + Polarity, OCx_EN=1

*Note: The states of the external I/O pins connected to the standard OCx channels depend on the state of the OCx channel and on the GPIO and AFIO registers.*

### 14.4.9 TIMx counter (TIMx\_CNT)

Address offset: 0x24

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CNT[15:0]**: Counter value

### 14.4.10 TIMx prescaler (TIMx\_PSC)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded into the active prescaler register at each update event.

### 14.4.11 TIMx auto-reload register (TIMx\_ARR)

Address offset: 0x2C

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to the [Section 14.3.1: Time-base unit on page 331](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 14.4.12 TIMx capture/compare register 1 (TIMx\_CCR1)

Address offset: 0x34

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded into the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (OC1PE bit). Else the preload value is copied into the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the TIMx\_CNT counter and signaled on the OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

### 14.4.13 TIMx capture/compare register 2 (TIMx\_CCR2) (available only for TIM9)

Address offset: 0x38

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded into the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (OC2PE bit). Else the preload value is copied into the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the TIMx\_CNT counter and signalled on the OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2).

### 14.4.14 TIM9 option register 1 (TIM9\_OR)

Address offset: 0x50

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														TI1_RMP	
														rw	

Bits 15:2 Reserved

Bits 1:0 **TI1\_RMP**: TIM9 input 1 remapping capability

Set and cleared by software.

00: TIM9 Channel1 is connected to GPIO: Refer to Alternate Function mapping

01: LSE external clock is connected to the TIM9\_CH1 input for measurement purposes

10: TIM9 Channel1 is connected to GPIO

11: TIM9 Channel1 is connected to GPIO

### 14.4.15 TIM10 option register 1 (TIM10\_OR)

Address offset: 0x50

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														T11_RMP	
														rw	

Bits 15:2 Reserved

Bits 1:0 **T11\_RMP**: TIM10 Input 1 remapping capability  
Set and cleared by software.

00: TIM10 Channel1 is connected to GPIO: Refer to Alternate Function mapping

01: LSI internal clock is connected to the TIM10\_CH1 input for measurement purposes

10: LSE external clock is connected to the TIM10\_CH1 input for measurement purposes

11: RTC output event is connected to the TIM10\_CH1 input for measurement purposes

### 14.4.16 TIM11 option register 1 (TIM11\_OR)

Address offset: 0x50

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														T11_RMP	
														rw	

Bits 15:2 Reserved

Bits 1:0 **T11\_RMP**: TIM11 Input 1 remapping capability  
Set and cleared by software.

00: TIM11 Channel1 is connected to GPIO: Refer to Alternate Function mapping

01: MSI internal clock is connected to the TIM11\_CH1 input for measurement purposes

10: HSE external clock (1MHz for RTC) is connected to the TIM11\_CH1 input for measurement purposes

11: TIM11 Channel1 is connected to GPIO

### 14.4.17 TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the tables below:

**Table 58. TIM9 register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

# 15 Basic timers (TIM6&TIM7)

## 15.1 TIM6&TIM7 introduction

The basic timers TIM6 and TIM7 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time-base generation but they are also specifically used to drive the digital-to-analog converter (DAC). In fact, the timers are internally connected to the DAC and are able to drive it through their trigger outputs.

The timers are completely independent, and do not share any resources.

## 15.2 TIM6&TIM7 main features

Basic timer (TIM6&TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

Figure 143. Basic timer block diagram

## 15.3 TIM6&TIM7 functional description

### 15.3.1 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx\_CNT)
- Prescaler Register (TIMx\_PSC)
- Auto-Reload Register (TIMx\_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx\_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx\_CR1 register is set.

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as the TIMx\_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 144* and *Figure 145* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 144. Counter timing diagram with prescaler division change from 1 to 2

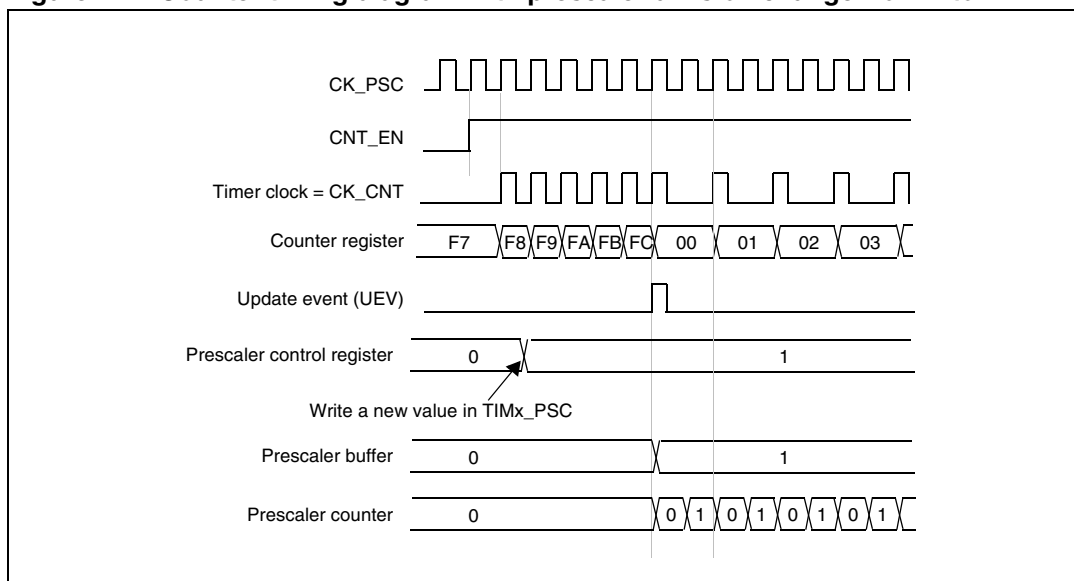

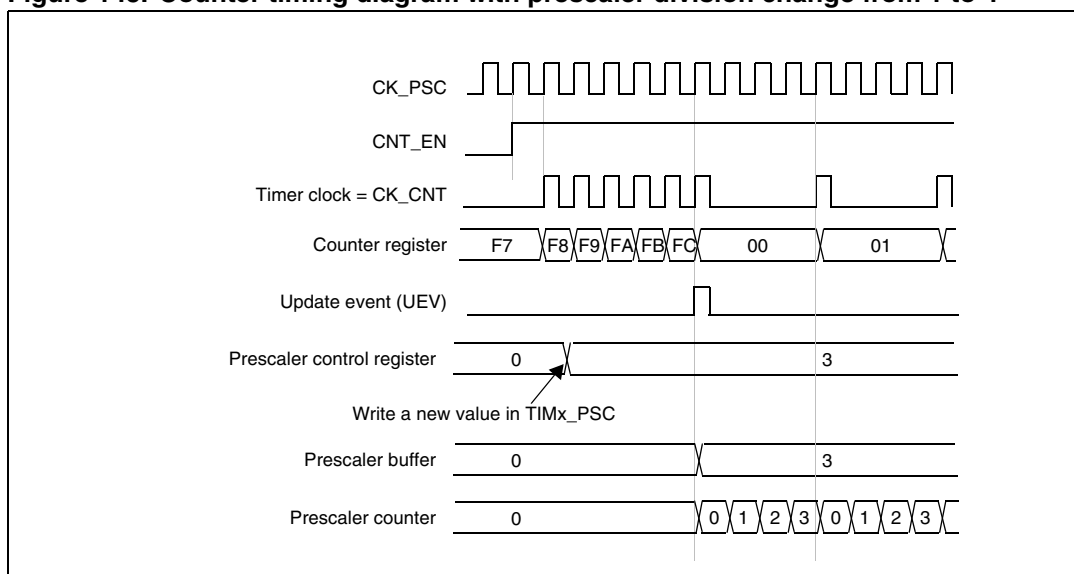

Figure 145. Counter timing diagram with prescaler division change from 1 to 4

### 15.3.2 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx\_CR1

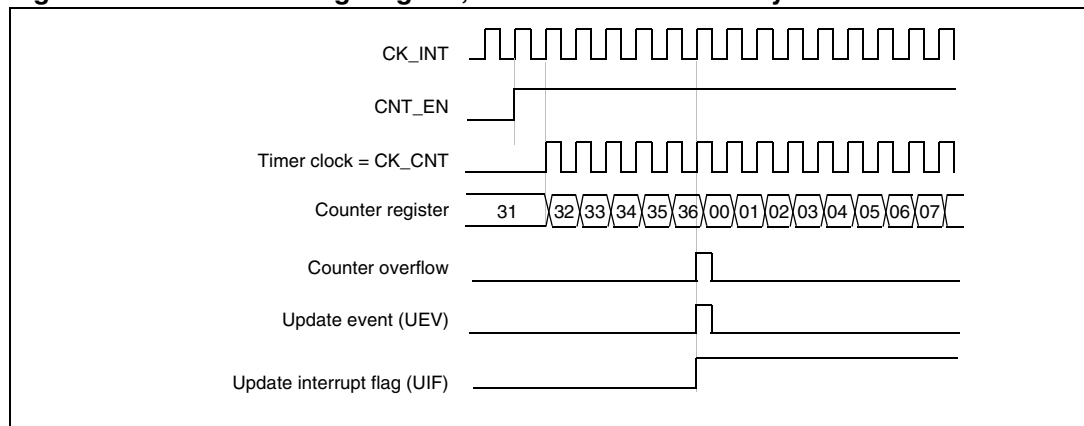

register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR = 0x36.

**Figure 146. Counter timing diagram, internal clock divided by 1**

**Figure 147. Counter timing diagram, internal clock divided by 2**

**Figure 148. Counter timing diagram, internal clock divided by 4**

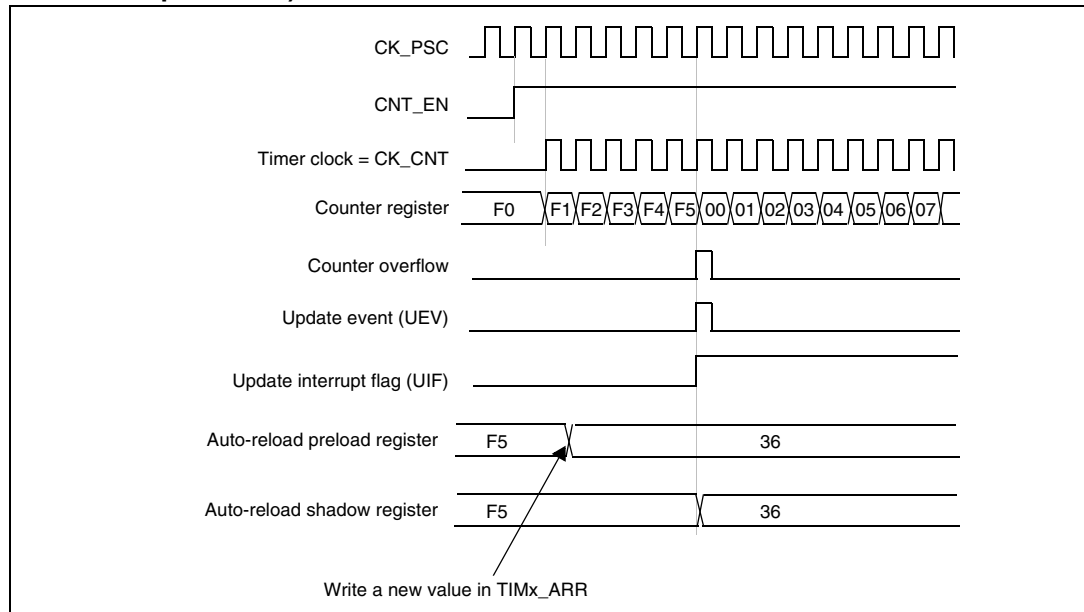

**Figure 149. Counter timing diagram, internal clock divided by N**

**Figure 150. Counter timing diagram, update event when ARPE = 0 (TIMx\_ARR not preloaded)**

**Figure 151. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

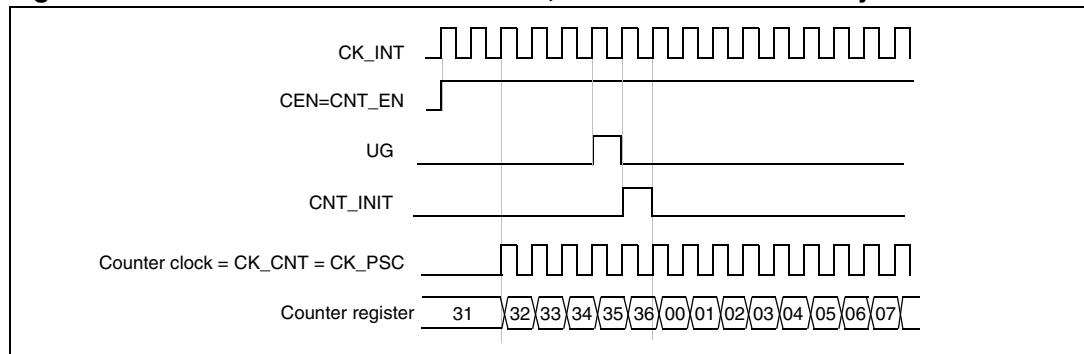

### 15.3.3 Clock source

The counter clock is provided by the Internal clock (CK\_INT) source.

The CEN (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

Figure 152 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 152. Control circuit in normal mode, internal clock divided by 1**

### 15.3.4 Debug mode

When the microcontroller enters the debug mode (Cortex-M3 core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG\_TIMx\_STOP configuration bit in the DBG module. For more details, refer to [Section 24.16.2: Debug support for timers, watchdog and I2C](#).

## 15.4 TIM6&TIM7 registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 15.4.1 TIM6&TIM7 control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								ARPE	Reserved				OPM	URS	UDIS	CEN
								rw					rw	rw	rw	rw

Bits 15:8 Reserved, always read as 0

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered.

1: TIMx\_ARR register is buffered.

Bits 6:4 Reserved, always read as 0

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

### 15.4.2 TIM6&TIM7 control register 2 (TIMx\_CR2)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									MMS[2:0]			Reserved			
									rw	rw	rw				

Bits 15:7 Reserved, always read as 0.

Bits 6:4 **MMS**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in the TIMx\_SMCR register).

010: **Update** - The update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

Bits 3:0 Reserved, always read as 0

### 15.4.3 TIM6&TIM7 DMA/Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							UDE	Reserved							UIE
							rw								rw

Bit 15:9 Reserved, always read as 0.

Bit 8 **UDE**: Update DMA request enable

0: Update DMA request disabled.

1: Update DMA request enabled.

Bit 7:1 Reserved, always read as 0.

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled.

1: Update interrupt enabled.

### 15.4.4 TIM6&TIM7 status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															UIF
															rc_w0

Bits 15:1 Reserved, always read as 0.

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow or underflow regarding the repetition counter value and if UDIS = 0 in the TIMx\_CR1 register.

- When CNT is reinitialized by software using the UG bit in the TIMx\_EGR register, if URS = 0 and UDIS = 0 in the TIMx\_CR1 register.

### 15.4.5 TIM6&TIM7 event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															UG
															w

Bits 15:1 Reserved, always read as 0.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

### 15.4.6 TIM6&TIM7 counter (TIMx\_CNT)

Address offset: 0x24

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CNT[15:0]**: Counter value

### 15.4.7 TIM6&TIM7 prescaler (TIMx\_PSC)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded into the active prescaler register at each update event.

### 15.4.8 TIM6&TIM7 auto-reload register (TIMx\_ARR)

Address offset: 0x2C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **ARR[15:0]**: Prescaler value

ARR is the value to be loaded into the actual auto-reload register.

Refer to [Section 15.3.1: Time-base unit on page 372](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 15.4.9 TIM6&TIM7 register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

**Table 60. TIM6&TIM7 register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
0x00	<b>TIMx_CR1</b> Reset value	Reserved																							0	ARPE	Reserved			0	OPM	0	URS	0	UDIS	0	CEN
0x04	<b>TIMx_CR2</b> Reset value	Reserved													MMS[2:0]			Reserved

0x0C	<b>TIMx_DIER</b> Reset value	Reserved																							0	UDE	Reserved			0	UIE						
0x10	<b>TIMx_SR</b> Reset value	Reserved																							0	UIF											
0x14	<b>TIMx_EGR</b> Reset value	Reserved																							0	UG											
0x18	Reserved																																				
0x1C	Reserved																																				
0x20	Reserved																																				
0x24	<b>TIMx_CNT</b> Reset value	Reserved													CNT[15:0]																						
		0   0																																			
0x28	<b>TIMx_PSC</b> Reset value	Reserved													PSC[15:0]																						
		0   0																																			
0x2C	<b>TIMx_ARR</b> Reset value	Reserved													ARR[15:0]																						
		0   0																																			

Refer to [Table 1 on page 32](#) for the register boundary addresses.

## 16 Independent watchdog (IWDG)

### 16.1 IWDG introduction

The STM32L15xxx have two embedded watchdog peripherals which offer a combination of high safety level, timing accuracy and flexibility of use. Both watchdog peripherals (Independent and Window) serve to detect and resolve malfunctions due to software failure, and to trigger system reset or an interrupt (window watchdog only) when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails. The window watchdog (WWDG) clock is prescaled from the APB1 clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The IWDG is best suited to applications which require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. The WWDG is best suited to applications which require the watchdog to react within an accurate timing window. For further information on the window watchdog, refer to [Section 17 on page 387](#).

### 16.2 IWDG main features

- Free-running downcounter
- clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Reset (if watchdog activated) when the downcounter value of 0x000 is reached

### 16.3 IWDG functional description

[Figure 153](#) shows the functional blocks of the independent watchdog module.

When the independent watchdog is started by writing the value 0xCCCC in the Key register (IWDG\_KR), the counter starts counting down from the reset value of 0xFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0xAAAA is written in the IWDG\_KR register, the IWDG\_RLR value is reloaded in the counter and the watchdog reset is prevented.

#### 16.3.1 Hardware watchdog

If the “Hardware watchdog” feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and will generate a reset unless the Key register is written by the software before the counter reaches end of count.

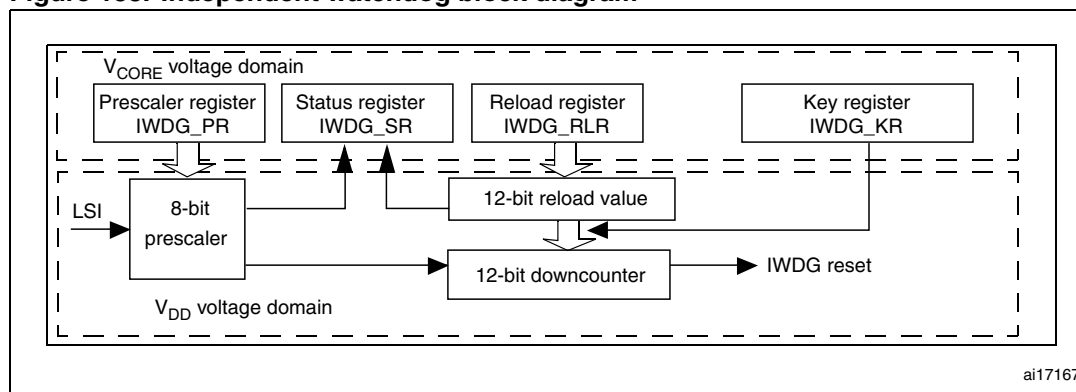

### 16.3.2 Register access protection

Write access to the IWDG\_PR and IWDG\_RLR registers is protected. To modify them, you must first write the code 0x5555 in the IWDG\_KR register. A write access to this register with a different value will break the sequence and register access will be protected again. This implies that it is the case of the reload operation (writing 0xAAAA). A status register is available to indicate that an update of the prescaler or the down-counter reload value is on going.

### 16.3.3 Debug mode

When the microcontroller enters debug mode (Cortex-M3 core halted), the IWDG counter either continues to work normally or stops, depending on DBG\_IWDG\_STOP configuration bit in DBG module. For more details, refer to [Section 24.16.2: Debug support for timers, watchdog and I2C](#).

Figure 153. Independent watchdog block diagram

Note: The watchdog function is implemented in the V<sub>DD</sub> voltage domain that is still functional in Stop and Standby modes.

Table 61. Min/max IWDG timeout period at 37 kHz (LSI) <sup>(1)</sup>

Prescaler divider	PR[2:0] bits	Min timeout (ms) RL[11:0]= 0x000	Max timeout (ms) RL[11:0]= 0xFFFF
/4	0	0.108	442.81
/8	1	0.216	885.621
/16	2	0.432	1771.243
/32	3	0.864	3542.486
/64	4	1.729	7084.972
/128	5	3.459	14169.945
/256	6	6.918	28339.891

1. These timings are given for a 37 kHz clock but the microcontroller’s internal RC frequency can vary from 30 to 60 kHz. Moreover, given an exact RC oscillator frequency, the exact timings still depend on the phasing of the APB interface clock versus the LSI clock so that there is always a full RC period of uncertainty.

## 16.4 IWDG registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 16.4.1 Key register (IWDG\_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

Bits 31:16 Reserved, read as 0.

Bits 15:0 **KEY[15:0]**: Key value (write only, read 0000h)

These bits must be written by software at regular intervals with the key value AAAAh, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 5555h to enable access to the IWDG\_PR and IWDG\_RLR registers (see [Section 16.3.2](#))

Writing the key value CCCCh starts the watchdog (except if the hardware watchdog option is selected)

### 16.4.2 Prescaler register (IWDG\_PR)

Address offset: 0x04

Reset value: 0x0000 0000

Bits 31:3 Reserved, read as 0.

Bits 2:0 **PR[2:0]**: Prescaler divider

These bits are write access protected see [Section 16.3.2](#). They are written by software to select the prescaler divider feeding the counter clock. PVU bit of IWDG\_SR must be reset in order to be able to change the prescaler divider.

000: divider /4

001: divider /8

010: divider /16

011: divider /32

100: divider /64

101: divider /128

110: divider /256

111: divider /256

*Note:* Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG\_SR register is reset.

### 16.4.3 Reload register (IWDG\_RLR)

Address offset: 0x08

Reset value: 0x0000 0FFF (reset by Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0											
Reserved												RL[11:0]																														
												rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, read as 0.

Bits11:0 **RL[11:0]**: Watchdog counter reload value

These bits are write access protected see [Section 16.3.2](#). They are written by software to define the value to be loaded in the watchdog counter each time the value AAAAh is written in the IWDG\_KR register. The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to [Table 61](#).

The RVU bit in the IWDG\_SR register must be reset in order to be able to change the reload value.

*Note: Reading this register returns the reload value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on this register. For this reason the value read from this register is valid only when the RVU bit in the IWDG\_SR register is reset.*

### 16.4.4 Status register (IWDG\_SR)

Address offset: 0x0C

Reset value: 0x0000 0000 (not reset by Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																RVU	PVU														
																r	r														

Bits 31:2 Reserved

Bit 1 **RVU**: Watchdog counter reload value update

This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the V<sub>DD</sub> voltage domain (takes up to 5 RC 40 kHz cycles).

Reload value can be updated only when RVU bit is reset.

Bit 0 **PVU**: Watchdog prescaler value update

This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the V<sub>DD</sub> voltage domain (takes up to 5 RC 40 kHz cycles).

Prescaler value can be updated only when PVU bit is reset.

*Note: If several reload values or prescaler values are used by application, it is mandatory to wait until RVU bit is reset before changing the reload value and to wait until PVU bit is reset before changing the prescaler value. However, after updating the prescaler and/or the reload value it is not necessary to wait until RVU or PVU is reset before continuing code execution (even in case of low-power mode entry, the write operation is taken into account and will complete)*

### 16.4.5 IWDG register map

The following table gives the IWDG register map and reset values.

**Table 62. IWDG register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Table 1 on page 32](#) for the register boundary addresses.

## 17 Window watchdog (WWDG)

### 17.1 WWDG introduction

The window watchdog is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the downcounter before the T6 bit becomes cleared. An MCU reset is also generated if the 7-bit downcounter value (in the control register) is refreshed before the downcounter has reached the window register value. This implies that the counter must be refreshed in a limited window.

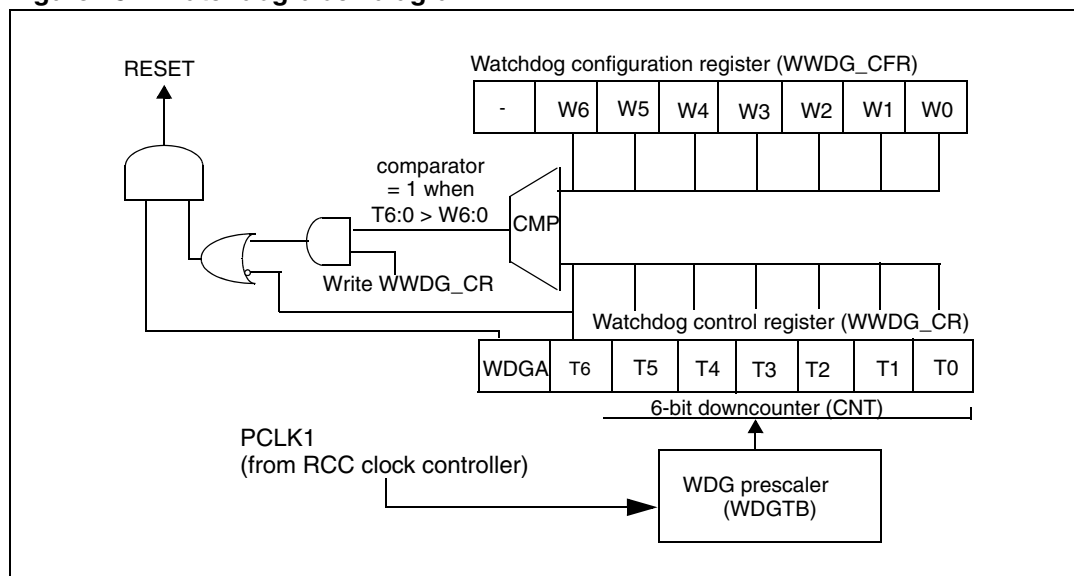

### 17.2 WWDG main features

- Programmable free-running downcounter
- Conditional reset
  - Reset (if watchdog activated) when the downcounter value becomes less than 40h
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window (see [Figure 155](#))
- Early wakeup interrupt (EWI): triggered (if enabled and the watchdog activated) when the downcounter is equal to 40h. Can be used to reload the counter and prevent WWDG reset

### 17.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG\_CR register) and when the 7-bit downcounter (T[6:0] bits) rolls over from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

Figure 154. Watchdog block diagram

The application program must write in the WWDG\_CR register at regular intervals during normal operation to prevent an MCU reset. This operation must occur only when the counter value is lower than the window register value. The value to be stored in the WWDG\_CR register must be between 0xFF and 0xC0:

- **Enabling the watchdog:**  
The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG\_CR register, then it cannot be disabled again except by a reset.
- **Controlling the downcounter:**  
This downcounter is free-running: It counts down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.  
The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WWDG\_CR register (see [Figure 155](#)).  
The Configuration register (WWDG\_CFR) contains the high limit of the window: To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x3F. [Figure 155](#) describes the window watchdog process.  
Another way to reload the counter is to use the early wakeup interrupt (EWI). This interrupt is enabled by setting the EWI bit in the WWDG\_CFR register. When the downcounter reaches the value 40h, this interrupt is generated and the corresponding interrupt service routine (ISR) can be used to reload the counter to prevent WWDG reset.  
This interrupt is cleared by writing '0' to the EWIF bit in the WWDG\_SR register.

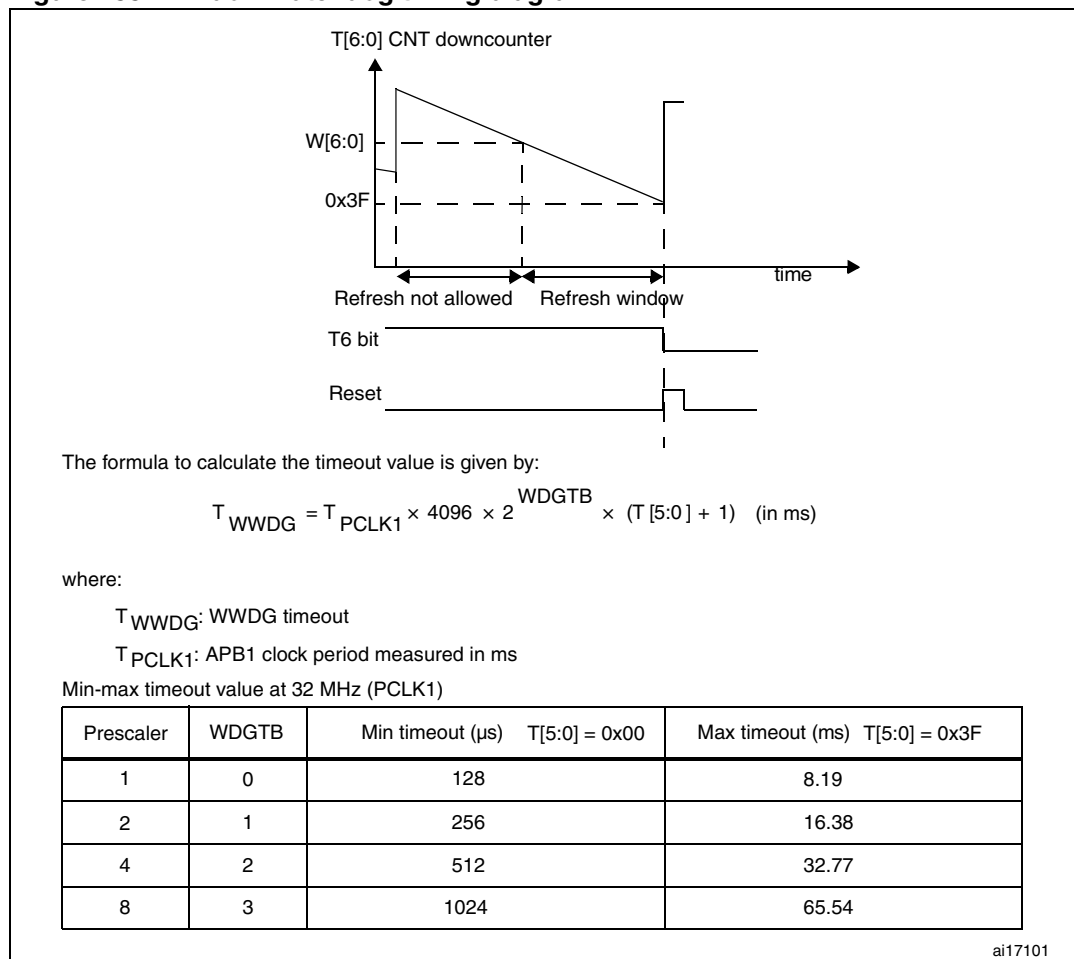

**Note:** *The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).*

## 17.4 How to program the watchdog timeout

You can use the formula in [Figure 155](#) to calculate the WWDG timeout.

**Warning:** When writing to the WWDG\_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.

**Figure 155. Window watchdog timing diagram**

## 17.5 Debug mode

When the microcontroller enters debug mode (Cortex-M3 core halted), the WWDG counter either continues to work normally or stops, depending on DBG\_WWDG\_STOP configuration bit in DBG module. For more details, refer to [Section 24.16.2: Debug support for timers, watchdog and I2C](#).

## 17.6 WWDG registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 17.6.1 Control register (WWDG\_CR)

Address offset: 0x00

Reset value: 0x7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								WDGA	T[6:0]						
								rs	rw						

Bits 31:8 Reserved

Bit 7 **WDGA**: Activation bit

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

Bits 6:0 **T[6:0]**: 7-bit counter (MSB to LSB)

These bits contain the value of the watchdog counter. It is decremented every  $(4096 \times 2^{WDGTB})$  PCLK1 cycles. A reset is produced when it rolls over from 40h to 3Fh (T6 becomes cleared).

### 17.6.2 Configuration register (WWDG\_CFR)

Address offset: 0x04

Reset value: 0x7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						EWI	WDGTB[1:0]		W[6:0]						
						rs	rw		rw						

Bit 31:10 Reserved

Bit 9 **EWI**: Early wakeup interrupt

When set, an interrupt occurs whenever the counter reaches the value 40h. This interrupt is only cleared by hardware after a reset.

Bits 8:7 **WDGTB[1:0]**: Timer base

The time base of the prescaler can be modified as follows:

- 00: CK Counter Clock (PCLK1 div 4096) div 1
- 01: CK Counter Clock (PCLK1 div 4096) div 2
- 10: CK Counter Clock (PCLK1 div 4096) div 4
- 11: CK Counter Clock (PCLK1 div 4096) div 8

Bits 6:0 **W[6:0]**: 7-bit window value

These bits contain the window value to be compared to the downcounter.

### 17.6.3 Status register (WWDG\_SR)

Address offset: 0x08

Reset value: 0x00

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														EWIF	
														rc_w0	

Bit 31:1Reserved

Bit 0 **EWIF**: Early wakeup interrupt flag

This bit is set by hardware when the counter has reached the value 40h. It must be cleared by software by writing '0. A write of '1 has no effect. This bit is also set if the interrupt is not enabled.

### 17.6.4 WWDG register map

The following table gives the WWDG register map and reset values.

**Table 63. WWDG register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
0x00	WWDG_CR	Reserved																							WDGA	T[6:0]								
	Reset value																								0	1	1	1	1	1	1	1		
0x04	WWDG_CFR	Reserved																							EWI	WDGTB1	WDGTB0	W[6:0]						
	Reset value																								0	0	0	1	1	1	1	1	1	1
0x08	WWDG_SR	Reserved																										EWIF						
	Reset value																											0						

Refer to [Table 1 on page 32](#) for the register boundary addresses.

## 18 Universal serial bus full-speed device interface (USB)

### 18.1 USB introduction

The USB peripheral implements an interface between a full-speed USB 2.0 bus and the APB1 bus.

USB suspend/resume are supported which allows to stop the device clocks for low-power consumption.

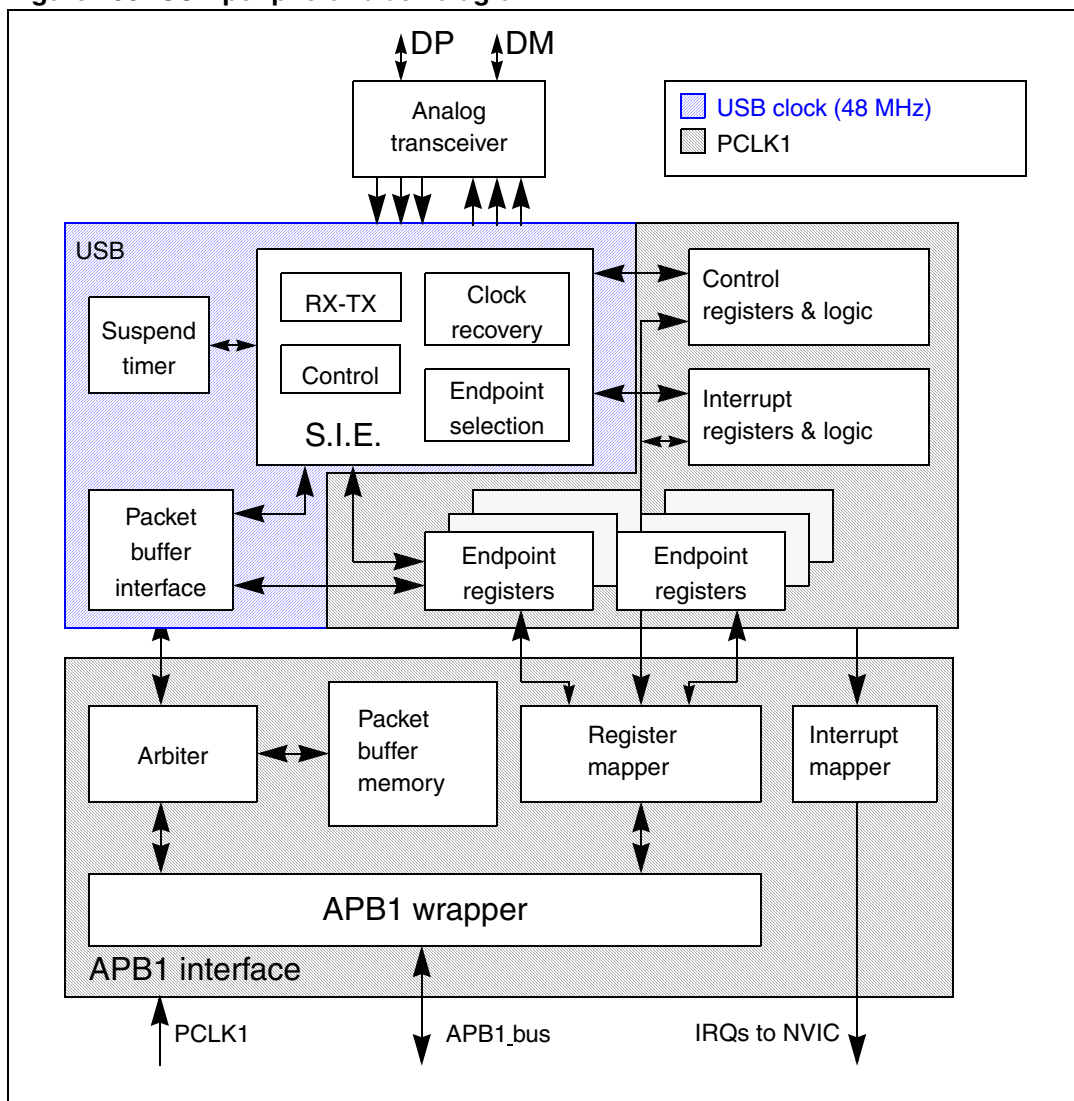

### 18.2 USB main features

- USB specification version 2.0 full-speed compliant
- Configurable number of endpoints from 1 to 8
- Cyclic redundancy check (CRC) generation/checking, Non-return-to-zero Inverted (NRZI) encoding/decoding and bit-stuffing
- Isochronous transfers support
- Double-buffered bulk/isochronous endpoint support
- USB Suspend/Resume operations
- Frame locked clock pulse generation
- USB internal connect/disconnect feature (controlled by system configuration register) with an internal pull-up resistor on the USB data+ (DP) line.

### 18.3 USB functional description

*Figure 156* shows the block diagram of the USB peripheral.

Figure 156. USB peripheral block diagram

The USB peripheral provides an USB compliant connection between the host PC and the function implemented by the microcontroller. Data transfer between the host PC and the system memory occurs through a dedicated packet buffer memory accessed directly by the USB peripheral. The size of this dedicated buffer memory must be according to the number of endpoints used and the maximum packet size. This dedicated memory is sized to 512 bytes and up to 16 mono-directional or 8 bidirectional endpoints can be used. The USB peripheral interfaces with the USB host, detecting token packets, handling data transmission/reception, and processing handshake packets as required by the USB standard. Transaction formatting is performed by the hardware, including CRC generation and checking.

Each endpoint is associated with a buffer description block indicating where the endpoint related memory area is located, how large it is or how many bytes must be transmitted. When a token for a valid function/endpoint pair is recognized by the USB peripheral, the related data transfer (if required and if the endpoint is configured) takes place. The data buffered by the USB peripheral is loaded in an internal 16 bit register and memory access to the dedicated buffer is performed. When all the data has been transferred, if needed, the

proper handshake packet over the USB is generated or expected according to the direction of the transfer.

At the end of the transaction, an endpoint-specific interrupt is generated, reading status registers and/or using different interrupt response routines. The microcontroller can determine:

- Which endpoint has to be served
- Which type of transaction took place, if errors occurred (bit stuffing, format, CRC, protocol, missing ACK, over/underrun, etc.)

Special support is offered to Isochronous transfers and high throughput bulk transfers, implementing a double buffer usage, which allows to always have an available buffer for the USB peripheral while the microcontroller uses the other one.

The unit can be placed in low-power mode (SUSPEND mode), by writing in the control register, whenever required. At this time, all static power dissipation is avoided, and the USB clock can be slowed down or stopped. The detection of activity at the USB inputs, while in low-power mode, wakes the device up asynchronously. A special interrupt source can be connected directly to a wakeup line to allow the system to immediately restart the normal clock generation and/or support direct clock start/stop.

### 18.3.1 Description of USB blocks

The USB peripheral implements all the features related to USB interfacing, which include the following blocks:

- **Serial Interface Engine (SIE):** The functions of this block include: synchronization pattern recognition, bit-stuffing, CRC generation and checking, PID verification/generation, and handshake evaluation. It must interface with the USB transceivers and uses the virtual buffers provided by the packet buffer interface for local data storage. This unit also generates signals according to USB peripheral events, such as Start of Frame (SOF), USB\_Reset, Data errors etc. and to Endpoint related events like end of transmission or correct reception of a packet; these signals are then used to generate interrupts.
- **Timer:** This block generates a start-of-frame locked clock pulse and detects a global suspend (from the host) when no traffic has been received for 3 ms.
- **Packet Buffer Interface:** This block manages the local memory implementing a set of buffers in a flexible way, both for transmission and reception. It can choose the proper buffer according to requests coming from the SIE and locate them in the memory addresses pointed by the Endpoint registers. It increments the address after each exchanged word until the end of packet, keeping track of the number of exchanged bytes and preventing the buffer to overrun the maximum capacity.
- **Endpoint-Related Registers:** Each endpoint has an associated register containing the endpoint type and its current status. For mono-directional/single-buffer endpoints, a single register can be used to implement two distinct endpoints. The number of registers is 8, allowing up to 16 mono-directional/single-buffer or up to 7 double-buffer endpoints\* in any combination. For example the USB peripheral can be programmed to have 4 double buffer endpoints and 8 single-buffer/mono-directional endpoints.

- Control Registers: These are the registers containing information about the status of the whole USB peripheral and used to force some USB events, such as resume and power-down.
- Interrupt Registers: These contain the Interrupt masks and a record of the events. They can be used to inquire an interrupt reason, the interrupt status or to clear the status of a pending interrupt.

*Note:* \* Endpoint 0 is always used for control transfer in single-buffer mode.

The USB peripheral is connected to the APB1 bus through an APB1 interface, containing the following blocks:

- Packet Memory: This is the local memory that physically contains the Packet Buffers. It can be used by the Packet Buffer interface, which creates the data structure and can be accessed directly by the application software. The size of the Packet Memory is 512 bytes, structured as 256 words by 16 bits.
- Arbiter: This block accepts memory requests coming from the APB1 bus and from the USB interface. It resolves the conflicts by giving priority to APB1 accesses, while always reserving half of the memory bandwidth to complete all USB transfers. This time-duplex scheme implements a virtual dual-port SRAM that allows memory access, while an USB transaction is happening. Multiword APB1 transfers of any length are also allowed by this scheme.
- Register Mapper: This block collects the various byte-wide and bit-wide registers of the USB peripheral in a structured 16-bit wide word set addressed by the APB1.
- APB1 Wrapper: This provides an interface to the APB1 for the memory and register. It also maps the whole USB peripheral in the APB1 address space.
- Interrupt Mapper: This block is used to select how the possible USB events can generate interrupts and map them to three different lines of the NVIC:
  - USB low-priority interrupt (Channel 20): Triggered by all USB events (Correct transfer, USB reset, etc.). The firmware has to check the interrupt source before serving the interrupt.
  - USB high-priority interrupt (Channel 19): Triggered only by a correct transfer event for isochronous and double-buffer bulk transfer to reach the highest possible transfer rate.
  - USB wakeup interrupt (Channel 42): Triggered by the wakeup event from the USB Suspend mode.

## 18.4 Programming considerations

In the following sections, the expected interactions between the USB peripheral and the application program are described, in order to ease application software development.

### 18.4.1 Generic USB device programming

This part describes the main tasks required of the application software in order to obtain USB compliant behavior. The actions related to the most general USB events are taken into account and paragraphs are dedicated to the special cases of double-buffered endpoints and Isochronous transfers. Apart from system reset, action is always initiated by the USB peripheral, driven by one of the USB events described below.

## 18.4.2 System and power-on reset

Upon system and power-on reset, the first operation the application software should perform is to provide all required clock signals to the USB peripheral and subsequently de-assert its reset signal so to be able to access its registers. The whole initialization sequence is hereafter described.

An internal pull-up resistor is connected to Data+ (DP) line and controlled by software using the USB\_PU bit in the SYSCFG\_PMC register of the SYSCFG module (refer to [Section 6: System configuration controller \(SYSCFG\) and routing interface \(RI\)](#)). When the USB\_PU bit is reset, no pull-up is connected to the DP line and the device cannot be detected on the USB bus (if no external pull-up is connected). When the USB\_PU bit is set, the internal pull-up is connected and the device can be detected on the USB bus.

As a first step application software needs to activate register macrocell clock and de-assert macrocell specific reset signal using related control bits provided by device clock management logic.

After that, the analog part of the device related to the USB transceiver must be switched on using the PDWN bit in CNTR register, which requires a special handling. This bit is intended to switch on the internal voltage references that supply the port transceiver. This circuit has a defined startup time ( $t_{\text{STARTUP}}$  specified in the datasheet) during which the behavior of the USB transceiver is not defined. It is thus necessary to wait this time, after setting the PDWN bit in the CNTR register, before removing the reset condition on the USB part (by clearing the FRES bit in the CNTR register). Clearing the ISTR register then removes any spurious pending interrupt before any other macrocell operation is enabled.

At system reset, the microcontroller must initialize all required registers and the packet buffer description table, to make the USB peripheral able to properly generate interrupts and data transfers. All registers not specific to any endpoint must be initialized according to the needs of application software (choice of enabled interrupts, chosen address of packet buffers, etc.). Then the process continues as for the USB reset case (see further paragraph).

### USB reset (RESET interrupt)

When this event occurs, the USB peripheral is put in the same conditions it is left by the system reset after the initialization described in the previous paragraph: communication is disabled in all endpoint registers (the USB peripheral will not respond to any packet). As a response to the USB reset event, the USB function must be enabled, having as USB address 0, implementing only the default control endpoint (endpoint address is 0 too). This is accomplished by setting the Enable Function (EF) bit of the USB\_DADDR register and initializing the EP0R register and its related packet buffers accordingly. During USB enumeration process, the host assigns a unique address to this device, which must be written in the ADD[6:0] bits of the USB\_DADDR register, and configures any other necessary endpoint.

When a RESET interrupt is received, the application software is responsible to enable again the default endpoint of USB function 0 within 10mS from the end of reset sequence which triggered the interrupt.

### Structure and usage of packet buffers

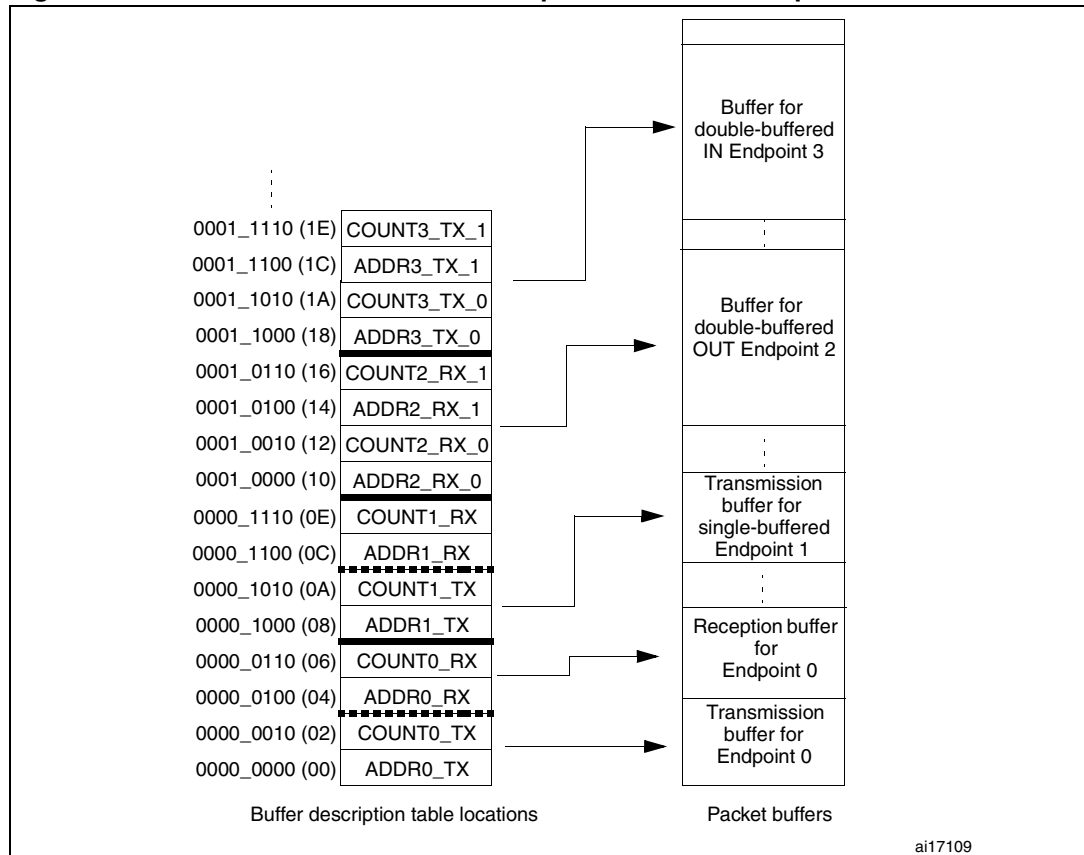

Each bidirectional endpoint may receive or transmit data from/to the host. The received data is stored in a dedicated memory buffer reserved for that endpoint, while another memory buffer contains the data to be transmitted by the endpoint. Access to this memory is

performed by the packet buffer interface block, which delivers a memory access request and waits for its acknowledgement. Since the packet buffer memory has to be accessed by the microcontroller also, an arbitration logic takes care of the access conflicts, using half APB1 cycle for microcontroller access and the remaining half for the USB peripheral access. In this way, both the agents can operate as if the packet memory is a dual-port SRAM, without being aware of any conflict even when the microcontroller is performing back-to-back accesses. The USB peripheral logic uses a dedicated clock. The frequency of this dedicated clock is fixed by the requirements of the USB standard at 48 MHz, and this can be different from the clock used for the interface to the APB1 bus. Different clock configurations are possible where the APB1 clock frequency can be higher or lower than the USB peripheral one.

*Note:* Due to USB data rate and packet memory interface requirements, the APB1 clock must have a minimum frequency of 10 MHz to avoid data overrun/underrun problems.

Each endpoint is associated with two packet buffers (usually one for transmission and the other one for reception). Buffers can be placed anywhere inside the packet memory because their location and size is specified in a buffer description table, which is also located in the packet memory at the address indicated by the USB\_BTABLE register. Each table entry is associated to an endpoint register and it is composed of four 16-bit words so that table start address must always be aligned to an 8-byte boundary (the lowest three bits of USB\_BTABLE register are always “000”). Buffer descriptor table entries are described in the [Section 18.5.3: Buffer descriptor table](#). If an endpoint is unidirectional and it is neither an Isochronous nor a double-buffered bulk, only one packet buffer is required (the one related to the supported transfer direction). Other table locations related to unsupported transfer directions or unused endpoints, are available to the user. Isochronous and double-buffered bulk endpoints have special handling of packet buffers (Refer to [Section 18.4.4: Isochronous transfers](#) and [Section 18.4.3: Double-buffered endpoints](#) respectively). The relationship between buffer description table entries and packet buffer areas is depicted in [Figure 157](#).

Figure 157. Packet buffer areas with examples of buffer description table locations

Each packet buffer is used either during reception or transmission starting from the bottom. The USB peripheral will never change the contents of memory locations adjacent to the allocated memory buffers; if a packet bigger than the allocated buffer length is received (buffer overrun condition) the data will be copied to the memory only up to the last available location.

### Endpoint initialization

The first step to initialize an endpoint is to write appropriate values to the ADDRn\_TX/ADDRn\_RX registers so that the USB peripheral finds the data to be transmitted already available and the data to be received can be buffered. The EP\_TYPE bits in the USB\_EPnR register must be set according to the endpoint type, eventually using the EP\_KIND bit to enable any special required feature. On the transmit side, the endpoint must be enabled using the STAT\_TX bits in the USB\_EPnR register and COUNTn\_TX must be initialized. For reception, STAT\_RX bits must be set to enable reception and COUNTn\_RX must be written with the allocated buffer size using the BL\_SIZE and NUM\_BLOCK fields. Unidirectional endpoints, except Isochronous and double-buffered bulk endpoints, need to initialize only bits and registers related to the supported direction. Once the transmission and/or reception are enabled, register USB\_EPnR and locations ADDRn\_TX/ADDRn\_RX, COUNTn\_TX/COUNTn\_RX (respectively), should not be modified by the application software, as the hardware can change their value on the fly. When the data transfer operation is completed, notified by a CTR interrupt event, they can be accessed again to re-enable a new operation.

### IN packets (data transmission)

When receiving an IN token packet, if the received address matches a configured and valid endpoint one, the USB peripheral accesses the contents of ADDRn\_TX and COUNTn\_TX locations inside buffer descriptor table entry related to the addressed endpoint. The content of these locations is stored in its internal 16 bit registers ADDR and COUNT (not accessible by software). The packet memory is accessed again to read the first word to be transmitted (Refer to [Structure and usage of packet buffers on page 397](#)) and starts sending a DATA0 or DATA1 PID according to USB\_EPnR bit DTOG\_TX. When the PID is completed, the first byte from the word, read from buffer memory, is loaded into the output shift register to be transmitted on the USB bus. After the last data byte is transmitted, the computed CRC is sent. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the data packet, according to STAT\_TX bits in the USB\_EPnR register.

The ADDR internal register is used as a pointer to the current buffer memory location while COUNT is used to count the number of remaining bytes to be transmitted. Each word read from the packet buffer memory is transmitted over the USB bus starting from the least significant byte. Transmission buffer memory is read starting from the address pointed by ADDRn\_TX for COUNTn\_TX/2 words. If a transmitted packet is composed of an odd number of bytes, only the lower half of the last word accessed will be used.

On receiving the ACK receipt by the host, the USB\_EPnR register is updated in the following way: DTOG\_TX bit is toggled, the endpoint is made invalid by setting STAT\_TX=10 (NAK) and bit CTR\_TX is set. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the EP\_ID and DIR bits in the USB\_ISTR register. Servicing of the CTR\_TX event starts clearing the interrupt bit; the application software then prepares another buffer full of data to be sent, updates the COUNTn\_TX table location with the number of byte to be transmitted during the next transfer, and finally sets STAT\_TX to '11 (VALID) to re-enable transmissions. While the STAT\_TX bits are equal to '10 (NAK), any IN request addressed to that endpoint is NAKed, indicating a flow control

condition: the USB host will retry the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second IN transaction addressed to the same endpoint immediately following the one which triggered the CTR interrupt.

### **OUT and SETUP packets (data reception)**

These two tokens are handled by the USB peripheral more or less in the same way; the differences in the handling of SETUP packets are detailed in the following paragraph about control transfers. When receiving an OUT/SETUP PID, if the address matches a valid endpoint, the USB peripheral accesses the contents of the ADDRn\_RX and COUNTn\_RX locations inside the buffer descriptor table entry related to the addressed endpoint. The content of the ADDRn\_RX is stored directly in its internal register ADDR. While COUNT is now reset and the values of BL\_SIZE and NUM\_BLOCK bit fields, which are read within COUNTn\_RX content are used to initialize BUF\_COUNT, an internal 16 bit counter, which is used to check the buffer overrun condition (all these internal registers are not accessible by software). Data bytes subsequently received by the USB peripheral are packed in words (the first byte received is stored as least significant byte) and then transferred to the packet buffer starting from the address contained in the internal ADDR register while BUF\_COUNT is decremented and COUNT is incremented at each byte transfer. When the end of DATA packet is detected, the correctness of the received CRC is tested and only if no errors occurred during the reception, an ACK handshake packet is sent back to the transmitting host. In case of wrong CRC or other kinds of errors (bit-stuff violations, frame errors, etc.), data bytes are still copied in the packet memory buffer, at least until the error detection point, but ACK packet is not sent and the ERR bit in USB\_ISTR register is set. However, there is usually no software action required in this case: the USB peripheral recovers from reception errors and remains ready for the next transaction to come. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the ACK, according to bits STAT\_RX in the USB\_EPnR register and no data is written in the reception memory buffers.

Reception memory buffer locations are written starting from the address contained in the ADDRn\_RX for a number of bytes corresponding to the received data packet length, CRC included (i.e. data payload length + 2), or up to the last allocated memory location, as defined by BL\_SIZE and NUM\_BLOCK, whichever comes first. In this way, the USB peripheral never writes beyond the end of the allocated reception memory buffer area. If the length of the data packet payload (actual number of bytes used by the application) is greater than the allocated buffer, the USB peripheral detects a buffer overrun condition. In this case, a STALL handshake is sent instead of the usual ACK to notify the problem to the host, no interrupt is generated and the transaction is considered failed.

When the transaction is completed correctly, by sending the ACK handshake packet, the internal COUNT register is copied back in the COUNTn\_RX location inside the buffer description table entry, leaving unaffected BL\_SIZE and NUM\_BLOCK fields, which normally do not require to be re-written, and the USB\_EPnR register is updated in the following way: DTOG\_RX bit is toggled, the endpoint is made invalid by setting STAT\_RX = '10 (NAK) and bit CTR\_RX is set. If the transaction has failed due to errors or buffer overrun condition, none of the previously listed actions take place. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the EP\_ID and DIR bits in the USB\_ISTR register. The CTR\_RX event is serviced by first determining the transaction type (SETUP bit in the USB\_EPnR register); the application software must clear the interrupt flag bit and get the number of received bytes reading the COUNTn\_RX location inside the buffer description table entry related to the endpoint being processed. After the received data is processed, the application software should set the STAT\_RX bits to '11 (Valid) in the USB\_EPnR, enabling further transactions. While the

STAT\_RX bits are equal to '10 (NAK), any OUT request addressed to that endpoint is NAKed, indicating a flow control condition: the USB host will retry the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second OUT transaction addressed to the same endpoint following immediately the one which triggered the CTR interrupt.

### Control transfers

Control transfers are made of a SETUP transaction, followed by zero or more data stages, all of the same direction, followed by a status stage (a zero-byte transfer in the opposite direction). SETUP transactions are handled by control endpoints only and are very similar to OUT ones (data reception) except that the values of DTOG\_TX and DTOG\_RX bits of the addressed endpoint registers are set to 1 and 0 respectively, to initialize the control transfer, and both STAT\_TX and STAT\_RX are set to '10 (NAK) to let software decide if subsequent transactions must be IN or OUT depending on the SETUP contents. A control endpoint must check SETUP bit in the USB\_EPnR register at each CTR\_RX event to distinguish normal OUT transactions from SETUP ones. A USB device can determine the number and direction of data stages by interpreting the data transferred in the SETUP stage, and is required to STALL the transaction in the case of errors. To do so, at all data stages before the last, the unused direction should be set to STALL, so that, if the host reverses the transfer direction too soon, it gets a STALL as a status stage. While enabling the last data stage, the opposite direction should be set to NAK, so that, if the host reverses the transfer direction (to perform the status stage) immediately, it is kept waiting for the completion of the control operation. If the control operation completes successfully, the software will change NAK to VALID, otherwise to STALL. At the same time, if the status stage will be an OUT, the STATUS\_OUT (EP\_KIND in the USB\_EPnR register) bit should be set, so that an error is generated if a status transaction is performed with not-zero data. When the status transaction is serviced, the application clears the STATUS\_OUT bit and sets STAT\_RX to VALID (to accept a new command) and STAT\_TX to NAK (to delay a possible status stage immediately following the next setup).

Since the USB specification states that a SETUP packet cannot be answered with a handshake different from ACK, eventually aborting a previously issued command to start the new one, the USB logic doesn't allow a control endpoint to answer with a NAK or STALL packet to a SETUP token received from the host.

When the STAT\_RX bits are set to '01 (STALL) or '10 (NAK) and a SETUP token is received, the USB accepts the data, performing the required data transfers and sends back an ACK handshake. If that endpoint has a previously issued CTR\_RX request not yet acknowledged by the application (i.e. CTR\_RX bit is still set from a previously completed reception), the USB discards the SETUP transaction and does not answer with any handshake packet regardless of its state, simulating a reception error and forcing the host to send the SETUP token again. This is done to avoid losing the notification of a SETUP transaction addressed to the same endpoint immediately following the transaction, which triggered the CTR\_RX interrupt.

### 18.4.3 Double-buffered endpoints

All different endpoint types defined by the USB standard represent different traffic models, and describe the typical requirements of different kind of data transfer operations. When large portions of data are to be transferred between the host PC and the USB function, the bulk endpoint type is the most suited model. This is because the host schedules bulk transactions so as to fill all the available bandwidth in the frame, maximizing the actual transfer rate as long as the USB function is ready to handle a bulk transaction addressed to it. If the USB function is still busy with the previous transaction when the next one arrives, it will answer with a NAK handshake and the host PC will issue the same transaction again until the USB function is ready to handle it, reducing the actual transfer rate due to the bandwidth occupied by re-transmissions. For this reason, a dedicated feature called 'double-buffering' can be used with bulk endpoints.

When 'double-buffering' is activated, data toggle sequencing is used to select, which buffer is to be used by the USB peripheral to perform the required data transfers, using both 'transmission' and 'reception' packet memory areas to manage buffer swapping on each successful transaction in order to always have a complete buffer to be used by the application, while the USB peripheral fills the other one. For example, during an OUT transaction directed to a 'reception' double-buffered bulk endpoint, while one buffer is being filled with new data coming from the USB host, the other one is available for the microcontroller software usage (the same would happen with a 'transmission' double-buffered bulk endpoint and an IN transaction).

Since the swapped buffer management requires the usage of all 4 buffer description table locations hosting the address pointer and the length of the allocated memory buffers, the USB\_EPnR registers used to implement double-buffered bulk endpoints are forced to be used as unidirectional ones. Therefore, only one STAT bit pair must be set at a value different from '00 (Disabled): STAT\_RX if the double-buffered bulk endpoint is enabled for reception, STAT\_TX if the double-buffered bulk endpoint is enabled for transmission. In case it is required to have double-buffered bulk endpoints enabled both for reception and transmission, two USB\_EPnR registers must be used.

To exploit the double-buffering feature and reach the highest possible transfer rate, the endpoint flow control structure, described in previous chapters, has to be modified, in order to switch the endpoint status to NAK only when a buffer conflict occurs between the USB peripheral and application software, instead of doing it at the end of each successful transaction. The memory buffer which is currently being used by the USB peripheral is defined by the DTOG bit related to the endpoint direction: DTOG\_RX (bit 14 of USB\_EPnR register) for 'reception' double-buffered bulk endpoints or DTOG\_TX (bit 6 of USB\_EPnR register) for 'transmission' double-buffered bulk endpoints. To implement the new flow control scheme, the USB peripheral should know which packet buffer is currently in use by the application software, so to be aware of any conflict. Since in the USB\_EPnR register, there are two DTOG bits but only one is used by USB peripheral for data and buffer sequencing (due to the unidirectional constraint required by double-buffering feature) the other one can be used by the application software to show which buffer it is currently using. This new buffer flag is called SW\_BUF. In the following table the correspondence between USB\_EPnR register bits and DTOG/SW\_BUF definition is explained, for the cases of 'transmission' and 'reception' double-buffered bulk endpoints.

**Table 64. Double-buffering buffer flag definition**

Buffer flag	'Transmission' endpoint	'Reception' endpoint
DTOG	DTOG_TX (USB_EPnRbit 6)	DTOG_RX (USB_EPnRbit 14)
SW_BUF	USB_EPnR bit 14	USB_EPnR bit 6

The memory buffer which is currently being used by the USB peripheral is defined by DTOG buffer flag, while the buffer currently in use by application software is identified by SW\_BUF buffer flag. The relationship between the buffer flag value and the used packet buffer is the same in both cases, and it is listed in the following table.

**Table 65. Bulk double-buffering memory buffers usage**

Endpoint Type	DTOG	SW_BUF	Packet buffer used by USB Peripheral	Packet buffer used by Application Software
IN	0	1	ADDRn_TX_0 / COUNTn_TX_0 Buffer description table locations.	ADDRn_TX_1 / COUNTn_TX_1 Buffer description table locations.
	1	0	ADDRn_TX_1 / COUNTn_TX_1 Buffer description table locations.	ADDRn_TX_0 / COUNTn_TX_0 Buffer description table locations.
	0	0	None <sup>(1)</sup>	ADDRn_TX_0 / COUNTn_TX_0 Buffer description table locations.
	1	1	None <sup>(1)</sup>	ADDRn_TX_0 / COUNTn_TX_0 Buffer description table locations.
OUT	0	1	ADDRn_RX_0 / COUNTn_RX_0 Buffer description table locations.	ADDRn_RX_1 / COUNTn_RX_1 Buffer description table locations.
	1	0	ADDRn_RX_1 / COUNTn_RX_1 Buffer description table locations.	ADDRn_RX_0 / COUNTn_RX_0 Buffer description table locations.
	0	0	None <sup>(1)</sup>	ADDRn_RX_0 / COUNTn_RX_0 Buffer description table locations.
	1	1	None <sup>(1)</sup>	ADDRn_RX_1 / COUNTn_RX_1 Buffer description table locations.

1. Endpoint in NAK Status.

Double-buffering feature for a bulk endpoint is activated by:

- Writing EP\_TYPE bit field at '00 in its USB\_EPnR register, to define the endpoint as a bulk, and
- Setting EP\_KIND bit at '1 (DBL\_BUF), in the same register.

The application software is responsible for DTOG and SW\_BUF bits initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. The end of the first transaction occurring after having set DBL\_BUF, triggers the special flow control of double-buffered bulk endpoints, which is used for all other transactions addressed to this endpoint until DBL\_BUF remain set. At the end of each transaction the CTR\_RX or CTR\_TX bit of the addressed endpoint USB\_EPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB\_EPnR register is hardware toggled making the USB peripheral buffer swapping completely software independent. Unlike common transactions, and the first one after

DBL\_BUF setting, STAT bit pair is not affected by the transaction termination and its value remains '11 (Valid). However, as the token packet of a new transaction is received, the actual endpoint status will be masked as '10 (NAK) when a buffer conflict between the USB peripheral and the application software is detected (this condition is identified by DTOG and SW\_BUF having the same value, see [Table 65 on page 404](#)). The application software responds to the CTR event notification by clearing the interrupt flag and starting any required handling of the completed transaction. When the application packet buffer usage is over, the software toggles the SW\_BUF bit, writing '1 to it, to notify the USB peripheral about the availability of that buffer. In this way, the number of NAKed transactions is limited only by the application elaboration time of a transaction data: if the elaboration time is shorter than the time required to complete a transaction on the USB bus, no re-transmissions due to flow control will take place and the actual transfer rate will be limited only by the host PC.

The application software can always override the special flow control implemented for double-buffered bulk endpoints, writing an explicit status different from '11 (Valid) into the STAT bit pair of the related USB\_EPnR register. In this case, the USB peripheral will always use the programmed endpoint status, regardless of the buffer usage condition.

#### 18.4.4 Isochronous transfers

The USB standard supports full speed peripherals requiring a fixed and accurate data production/consume frequency, defining this kind of traffic as 'Isochronous'. Typical examples of this data are: audio samples, compressed video streams, and in general any sort of sampled data having strict requirements for the accuracy of delivered frequency. When an endpoint is defined to be 'isochronous' during the enumeration phase, the host allocates in the frame the required bandwidth and delivers exactly one IN or OUT packet each frame, depending on endpoint direction. To limit the bandwidth requirements, no re-transmission of failed transactions is possible for Isochronous traffic; this leads to the fact that an isochronous transaction does not have a handshake phase and no ACK packet is expected or sent after the data packet. For the same reason, Isochronous transfers do not support data toggle sequencing and always use DATA0 PID to start any data packet.

The Isochronous behavior for an endpoint is selected by setting the EP\_TYPE bits at '10 in its USB\_EPnR register; since there is no handshake phase the only legal values for the STAT\_RX/STAT\_TX bit pairs are '00 (Disabled) and '11 (Valid), any other value will produce results not compliant to USB standard. Isochronous endpoints implement double-buffering to ease application software development, using both 'transmission' and 'reception' packet memory areas to manage buffer swapping on each successful transaction in order to have always a complete buffer to be used by the application, while the USB peripheral fills the other.

The memory buffer which is currently used by the USB peripheral is defined by the DTOG bit related to the endpoint direction (DTOG\_RX for 'reception' isochronous endpoints, DTOG\_TX for 'transmission' isochronous endpoints, both in the related USB\_EPnR register) according to [Table 66](#).

**Table 66. Isochronous memory buffers usage**

Endpoint Type	DTOG bit value	Packet buffer used by the USB peripheral	Packet buffer used by the application software
IN	0	ADDRn_TX_0 / COUNTn_TX_0 buffer description table locations.	ADDRn_TX_1 / COUNTn_TX_1 buffer description table locations.
	1	ADDRn_TX_1 / COUNTn_TX_1 buffer description table locations.	ADDRn_TX_0 / COUNTn_TX_0 buffer description table locations.
OUT	0	ADDRn_RX_0 / COUNTn_RX_0 buffer description table locations.	ADDRn_RX_1 / COUNTn_RX_1 buffer description table locations.
	1	ADDRn_RX_1 / COUNTn_RX_1 buffer description table locations.	ADDRn_RX_0 / COUNTn_RX_0 buffer description table locations.

As it happens with double-buffered bulk endpoints, the USB\_EPnR registers used to implement Isochronous endpoints are forced to be used as unidirectional ones. In case it is required to have Isochronous endpoints enabled both for reception and transmission, two USB\_EPnR registers must be used.

The application software is responsible for the DTOG bit initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. At the end of each transaction, the CTR\_RX or CTR\_TX bit of the addressed endpoint USB\_EPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB\_EPnR register is hardware toggled making buffer swapping completely software independent. STAT bit pair is not affected by transaction completion; since no flow control is possible for Isochronous transfers due to the lack of handshake phase, the endpoint remains always '11 (Valid). CRC errors or buffer-overflow conditions occurring during Isochronous OUT transfers are anyway considered as correct transactions and they always trigger an CTR\_RX event. However, CRC errors will anyway set the ERR bit in the USB\_ISTR register to notify the software of the possible data corruption.

### 18.4.5 Suspend/Resume events

The USB standard defines a special peripheral state, called SUSPEND, in which the average current drawn from the USB bus must not be greater than 500 µA. This requirement is of fundamental importance for bus-powered devices, while self-powered devices are not required to comply to this strict power consumption constraint. In suspend mode, the host PC sends the notification to not send any traffic on the USB bus for more than 3mS: since a SOF packet must be sent every mS during normal operations, the USB peripheral detects the lack of 3 consecutive SOF packets as a suspend request from the host PC and set the SUSP bit to '1 in USB\_ISTR register, causing an interrupt if enabled. Once the device is suspended, its normal operation can be restored by a so called RESUME sequence, which can be started from the host PC or directly from the peripheral itself, but it is always terminated by the host PC. The suspended USB peripheral must be anyway able to detect a RESET sequence, reacting to this event as a normal USB reset event.

The actual procedure used to suspend the USB peripheral is device dependent since according to the device composition, different actions may be required to reduce the total consumption.

A brief description of a typical suspend procedure is provided below, focused on the USB-related aspects of the application software routine responding to the SUSP notification of the USB peripheral:

1. Set the FSUSP bit in the USB\_CNTR register to 1. This action activates the suspend mode within the USB peripheral. As soon as the suspend mode is activated, the check on SOF reception is disabled to avoid any further SUSP interrupts being issued while the USB is suspended.
2. Remove or reduce any static power consumption in blocks different from the USB peripheral.
3. Set LP\_MODE bit in USB\_CNTR register to 1 to remove static power consumption in the analog USB transceivers but keeping them able to detect resume activity.
4. Optionally turn off external oscillator and device PLL to stop any activity inside the device.

When an USB event occurs while the device is in SUSPEND mode, the RESUME procedure must be invoked to restore nominal clocks and regain normal USB behavior. Particular care must be taken to insure that this process does not take more than 10mS when the waking event is an USB reset sequence (See “Universal Serial Bus Specification” for more details). The start of a resume or reset sequence, while the USB peripheral is suspended, clears the LP\_MODE bit in USB\_CNTR register asynchronously. Even if this event can trigger an WKUP interrupt if enabled, the use of an interrupt response routine must be carefully evaluated because of the long latency due to system clock restart; to have the shorter latency before re-activating the nominal clock it is suggested to put the resume procedure just after the end of the suspend one, so its code is immediately executed as soon as the system clock restarts. To prevent ESD discharges or any other kind of noise from waking-up the system (the exit from suspend mode is an asynchronous event), a suitable analog filter on data line status is activated during suspend; the filter width is about 70ns.

The following is a list of actions a resume procedure should address:

1. Optionally turn on external oscillator and/or device PLL.
2. Clear FSUSP bit of USB\_CNTR register.
3. If the resume triggering event has to be identified, bits RXDP and RXDM in the USB\_FNR register can be used according to [Table 67](#), which also lists the intended software action in all the cases. If required, the end of resume or reset sequence can be detected monitoring the status of the above mentioned bits by checking when they reach the “10” configuration, which represent the Idle bus state; moreover at the end of a reset sequence the RESET bit in USB\_ISTR register is set to 1, issuing an interrupt if enabled, which should be handled as usual.

**Table 67. Resume event detection**

[RXDP,RXDM] status	Wakeup event	Required resume software action
“00”	Root reset	None
“10”	None (noise on bus)	Go back in Suspend mode
“01”	Root resume	None
“11”	Not allowed (noise on bus)	Go back in Suspend mode

A device may require to exit from suspend mode as an answer to particular events not directly related to the USB protocol (e.g. a mouse movement wakes up the whole system). In this case, the resume sequence can be started by setting the RESUME bit in the USB\_CNTR register to '1 and resetting it to 0 after an interval between 1mS and 15mS (this interval can be timed using ESOE interrupts, occurring with a 1mS period when the system clock is running at nominal frequency). Once the RESUME bit is clear, the resume sequence will be completed by the host PC and its end can be monitored again using the RXDP and RXDM bits in the USB\_FNR register.

*Note:* The RESUME bit must be anyway used only after the USB peripheral has been put in suspend mode, setting the FSUSP bit in USB\_CNTR register to 1.

## 18.5 USB registers

The USB peripheral registers can be divided into the following groups:

- Common Registers: Interrupt and Control registers
- Endpoint Registers: Endpoint configuration and status
- Buffer Descriptor Table: Location of packet memory used to locate data buffers

All register addresses are expressed as offsets with respect to the USB peripheral registers base address 0x4000 5C00, except the buffer descriptor table locations, which starts at the address specified by the USB\_BTABLE register. Due to the common limitation of APB1 bridges on word addressability, all register addresses are aligned to 32-bit word boundaries although they are 16-bit wide. The same address alignment is used to access packet buffer memory locations, which are located starting from 0x4000 6000.

Refer to [Section 1.1 on page 29](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 18.5.1 Common registers

These registers affect the general behavior of the USB peripheral defining operating mode, interrupt handling, device address and giving access to the current frame number updated by the host PC.

#### USB control register (USB\_CNTR)

Address offset: 0x40

Reset value: 0x0003

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTRM	PMAOVRM	ERRM	WKUPM	SUSPM	RESETM	SOFM	ESOFM	Reserved			RESUME	FSUSP	LP_MODE	PDWN	FRES
rw	rw	rw	rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

- Bit 15 **CTRM**: Correct transfer interrupt mask  
 0: Correct Transfer (CTR) Interrupt disabled.  
 1: CTR Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
  - Bit 14 **PMAOVRM**: Packet memory area over / underrun interrupt mask  
 0: PMAOVR Interrupt disabled.  
 1: PMAOVR Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
  - Bit 13 **ERRM**: Error interrupt mask  
 0: ERR Interrupt disabled.  
 1: ERR Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
  - Bit 12 **WKUPM**: Wakeup interrupt mask  
 0: WKUP Interrupt disabled.  
 1: WKUP Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
  - Bit 11 **SUSPM**: Suspend mode interrupt mask  
 0: Suspend Mode Request (SUSP) Interrupt disabled.  
 1: SUSP Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
  - Bit 10 **RESETM**: USB reset interrupt mask  
 0: RESET Interrupt disabled.  
 1: RESET Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
  - Bit 9 **SOFM**: Start of frame interrupt mask  
 0: SOF Interrupt disabled.  
 1: SOF Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
  - Bit 8 **ESOFM**: Expected start of frame interrupt mask  
 0: Expected Start of Frame (ESOF) Interrupt disabled.  
 1: ESOF Interrupt enabled, an interrupt request is generated when the corresponding bit in the USB\_ISTR register is set.
- Bits 7:5 Reserved.

**Bit 4 RESUME:** Resume request

The microcontroller can set this bit to send a Resume signal to the host. It must be activated, according to USB specifications, for no less than 1mS and no more than 15mS after which the Host PC is ready to drive the resume sequence up to its end.

**Bit 3 FSUSP:** Force suspend

Software must set this bit when the SUSP interrupt is received, which is issued when no traffic is received by the USB peripheral for 3 mS.

0: No effect.

1: Enter suspend mode. Clocks and static power dissipation in the analog transceiver are left unaffected. If suspend power consumption is a requirement (bus-powered device), the application software should set the LP\_MODE bit after FSUSP as explained below.

**Bit 2 LP\_MODE:** Low-power mode

This mode is used when the suspend-mode power constraints require that all static power dissipation is avoided, except the one required to supply the external pull-up resistor. This condition should be entered when the application is ready to stop all system clocks, or reduce their frequency in order to meet the power consumption requirements of the USB suspend condition. The USB activity during the suspend mode (WKUP event) asynchronously resets this bit (it can also be reset by software).

0: No Low-power mode.

1: Enter Low-power mode.

**Bit 1 PDWN:** Power down

This bit is used to completely switch off all USB-related analog parts if it is required to completely disable the USB peripheral for any reason. When this bit is set, the USB peripheral is disconnected from the transceivers and it cannot be used.

0: Exit Power Down.

1: Enter Power down mode.

**Bit 0 FRES:** Force USB Reset

0: Clear USB reset.

1: Force a reset of the USB peripheral, exactly like a RESET signalling on the USB. The USB peripheral is held in RESET state until software clears this bit. A "USB-RESET" interrupt is generated, if enabled.

**USB interrupt status register (USB\_ISTR)**

Address offset: 0x44

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
CTR	PMA OVR	ERR	WKUP	SUSP	RESET	SOF	ESOF	Reserved				DIR	EP_ID[3:0]			
r	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0					r	r	r	r	r

This register contains the status of all the interrupt sources allowing application software to determine, which events caused an interrupt request.

The upper part of this register contains single bits, each of them representing a specific event. These bits are set by the hardware when the related event occurs; if the corresponding bit in the USB\_CNTR register is set, a generic interrupt request is generated. The interrupt routine, examining each bit, will perform all necessary actions, and finally it will clear the serviced bits. If any of them is not cleared, the interrupt is considered to be still pending, and the interrupt line will be kept high again. If several bits are set simultaneously, only a single interrupt will be generated.

Endpoint transaction completion can be handled in a different way to reduce interrupt response latency. The CTR bit is set by the hardware as soon as an endpoint successfully completes a transaction, generating a generic interrupt request if the corresponding bit in USB\_CNTR is set. An endpoint dedicated interrupt condition is activated independently from the CTRM bit in the USB\_CNTR register. Both interrupt conditions remain active until software clears the pending bit in the corresponding USB\_EPnR register (the CTR bit is actually a read only bit). For endpoint-related interrupts, the software can use the Direction of Transaction (DIR) and EP\_ID read-only bits to identify, which endpoint made the last interrupt request and called the corresponding interrupt service routine.

The user can choose the relative priority of simultaneously pending USB\_ISTR events by specifying the order in which software checks USB\_ISTR bits in an interrupt service routine. Only the bits related to events, which are serviced, are cleared. At the end of the service routine, another interrupt will be requested, to service the remaining conditions.

To avoid spurious clearing of some bits, it is recommended to clear them with a load instruction where all bits which must not be altered are written with 1, and all bits to be cleared are written with '0 (these bits can only be cleared by software). Read-modify-write cycles should be avoided because between the read and the write operations another bit could be set by the hardware and the next write will clear it before the microprocessor has the time to serve the event.

The following describes each bit in detail:

Bit 15 **CTR**: Correct transfer

This bit is set by the hardware to indicate that an endpoint has successfully completed a transaction; using DIR and EP\_ID bits software can determine which endpoint requested the interrupt. This bit is read-only.

Bit 14 **PMAOVR**: Packet memory area over / underrun

This bit is set if the microcontroller has not been able to respond in time to an USB memory request. The USB peripheral handles this event in the following way: During reception an ACK handshake packet is not sent, during transmission a bit-stuff error is forced on the transmitted stream; in both cases the host will retry the transaction. The PMAOVR interrupt should never occur during normal operations. Since the failed transaction is retried by the host, the application software has the chance to speed-up device operations during this interrupt handling, to be ready for the next transaction retry; however this does not happen during Isochronous transfers (no isochronous transaction is anyway retried) leading to a loss of data in this case. This bit is read/write but only '0 can be written and writing '1 has no effect.

Bit 13 **ERR**: Error

This flag is set whenever one of the errors listed below has occurred:

NANS: No ANSwer. The timeout for a host response has expired.

CRC: Cyclic Redundancy Check error. One of the received CRCs, either in the token or in the data, was wrong.

BST: Bit Stuffing error. A bit stuffing error was detected anywhere in the PID, data, and/or CRC.

FVIO: Framing format Violation. A non-standard frame was received (EOP not in the right place, wrong token sequence, etc.).

The USB software can usually ignore errors, since the USB peripheral and the PC host manage retransmission in case of errors in a fully transparent way. This interrupt can be useful during the software development phase, or to monitor the quality of transmission over the USB bus, to flag possible problems to the user (e.g. loose connector, too noisy environment, broken conductor in the USB cable and so on). This bit is read/write but only '0 can be written and writing '1 has no effect.

Bit 12 **WKUP**: Wakeup

This bit is set to 1 by the hardware when, during suspend mode, activity is detected that wakes up the USB peripheral. This event asynchronously clears the LP\_MODE bit in the CTLR register and activates the USB\_WAKEUP line, which can be used to notify the rest of the device (e.g. wakeup unit) about the start of the resume process. This bit is read/write but only '0 can be written and writing '1 has no effect.

Bit 11 **SUSP**: Suspend mode request

This bit is set by the hardware when no traffic has been received for 3mS, indicating a suspend mode request from the USB bus. The suspend condition check is enabled immediately after any USB reset and it is disabled by the hardware when the suspend mode is active (FSUSP=1) until the end of resume sequence. This bit is read/write but only '0 can be written and writing '1 has no effect.

**Bit 10 RESET:** USB reset request

Set when the USB peripheral detects an active USB RESET signal at its inputs. The USB peripheral, in response to a RESET, just resets its internal protocol state machine, generating an interrupt if RESETM enable bit in the USB\_CNTR register is set. Reception and transmission are disabled until the RESET bit is cleared. All configuration registers do not reset: the microcontroller must explicitly clear these registers (this is to ensure that the RESET interrupt can be safely delivered, and any transaction immediately followed by a RESET can be completed). The function address and endpoint registers are reset by an USB reset event.

This bit is read/write but only '0 can be written and writing '1 has no effect.

**Bit 9 SOF:** Start of frame

This bit signals the beginning of a new USB frame and it is set when a SOF packet arrives through the USB bus. The interrupt service routine may monitor the SOF events to have a 1mS synchronization event to the USB host and to safely read the USB\_FNR register which is updated at the SOF packet reception (this could be useful for isochronous applications).

This bit is read/write but only '0 can be written and writing '1 has no effect.

**Bit 8 ESOF:** Expected start of frame

This bit is set by the hardware when an SOF packet is expected but not received. The host sends an SOF packet each mS, but if the hub does not receive it properly, the Suspend Timer issues this interrupt. If three consecutive ESOF interrupts are generated (i.e. three SOF packets are lost) without any traffic occurring in between, a SUSP interrupt is generated. This bit is set even when the missing SOF packets occur while the Suspend Timer is not yet locked. This bit is read/write but only '0 can be written and writing '1 has no effect.

Bits 7:5 Reserved.

**Bit 4 DIR:** Direction of transaction

This bit is written by the hardware according to the direction of the successful transaction, which generated the interrupt request.

If DIR bit=0, CTR\_TX bit is set in the USB\_EPnR register related to the interrupting endpoint. The interrupting transaction is of IN type (data transmitted by the USB peripheral to the host PC).

If DIR bit=1, CTR\_RX bit or both CTR\_TX/CTR\_RX are set in the USB\_EPnR register related to the interrupting endpoint. The interrupting transaction is of OUT type (data received by the USB peripheral from the host PC) or two pending transactions are waiting to be processed.

This information can be used by the application software to access the USB\_EPnR bits related to the triggering transaction since it represents the direction having the interrupt pending. This bit is read-only.

**Bits 3:0 EP\_ID[3:0]:** Endpoint Identifier

These bits are written by the hardware according to the endpoint number, which generated the interrupt request. If several endpoint transactions are pending, the hardware writes the endpoint identifier related to the endpoint having the highest priority defined in the following way: Two endpoint sets are defined, in order of priority: Isochronous and double-buffered bulk endpoints are considered first and then the other endpoints are examined. If more than one endpoint from the same set is requesting an interrupt, the EP\_ID bits in USB\_ISTR register are assigned according to the lowest requesting endpoint register, EP0R having the highest priority followed by EP1R and so on. The application software can assign a register to each endpoint according to this priority scheme, so as to order the concurring endpoint requests in a suitable way. These bits are read only.

**USB frame number register (USB\_FNR)**

Address offset: 0x48

Reset value: 0x0XXX where X is undefined

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXDP	RXDM	LCK	LSOF[1:0]		FN[10:0]										
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 15 **RXDP**: Receive data + line status

This bit can be used to observe the status of received data plus upstream port data line. It can be used during end-of-suspend routines to help determining the wakeup event.

Bit 14 **RXDM**: Receive data - line status

This bit can be used to observe the status of received data minus upstream port data line. It can be used during end-of-suspend routines to help determining the wakeup event.

Bit 13 **LCK**: Locked

This bit is set by the hardware when at least two consecutive SOF packets have been received after the end of an USB reset condition or after the end of an USB resume sequence. Once locked, the frame timer remains in this state until an USB reset or USB suspend event occurs.

Bits 12:11 **LSOF[1:0]**: Lost SOF

These bits are written by the hardware when an ESOF interrupt is generated, counting the number of consecutive SOF packets lost. At the reception of an SOF packet, these bits are cleared.

Bits 10:0 **FN[10:0]**: Frame number

This bit field contains the 11-bits frame number contained in the last received SOF packet. The frame number is incremented for every frame sent by the host and it is useful for Isochronous transfers. This bit field is updated on the generation of an SOF interrupt.

**USB device address (USB\_DADDR)**

Address offset: 0x4C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								EF	ADD6	ADD5	ADD4	ADD3	ADD2	ADD1	ADD0
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:8 Reserved

Bit 7 **EF**: Enable function

This bit is set by the software to enable the USB device. The address of this device is contained in the following ADD[6:0] bits. If this bit is at '0 no transactions are handled, irrespective of the settings of USB\_EPnR registers.

Bits 6:0 **ADD[6:0]**: Device address

These bits contain the USB function address assigned by the host PC during the enumeration process. Both this field and the Endpoint Address (EA) field in the associated USB\_EPnR register must match with the information contained in a USB token in order to handle a transaction to the required endpoint.

**Buffer table address (USB\_BTABLE)**

Address offset: 0x50

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BTABLE[15:3]													Reserved		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 15:3 **BTABLE[15:3]**: Buffer table

These bits contain the start address of the buffer allocation table inside the dedicated packet memory. This table describes each endpoint buffer location and size and it must be aligned to an 8 byte boundary (the 3 least significant bits are always '0'). At the beginning of every transaction addressed to this device, the USP peripheral reads the element of this table related to the addressed endpoint, to get its buffer start location and the buffer size (Refer to [Structure and usage of packet buffers on page 397](#)).

Bits 2:0 Reserved, forced by hardware to 0.

### 18.5.2 Endpoint-specific registers

The number of these registers varies according to the number of endpoints that the USB peripheral is designed to handle. The USB peripheral supports up to 8 bidirectional endpoints. Each USB device must support a control endpoint whose address (EA bits) must be set to 0. The USB peripheral behaves in an undefined way if multiple endpoints are enabled having the same endpoint number value. For each endpoint, an USB\_EPnR register is available to store the endpoint specific information.

#### USB endpoint n register (USB\_EPnR), n=[0..7]

Address offset: 0x00 to 0x1C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
CTR_RX	DTOG_RX	STAT_RX[1:0]			SETUP	EP_TYPE[1:0]		EP_KIND	CTR_TX	DTOG_TX	STAT_TX[1:0]			EA[3:0]		
rc_w0	t	t	t	r	rw	rw	rw	rc_w0	t	t	t	rw	rw	rw	rw	

They are also reset when an USB reset is received from the USB bus or forced through bit FRES in the CTLR register, except the CTR\_RX and CTR\_TX bits, which are kept unchanged to avoid missing a correct packet notification immediately followed by an USB reset event. Each endpoint has its USB\_EPnR register where n is the endpoint identifier.

Read-modify-write cycles on these registers should be avoided because between the read and the write operations some bits could be set by the hardware and the next write would modify them before the CPU has the time to detect the change. For this purpose, all bits affected by this problem have an ‘invariant’ value that must be used whenever their modification is not required. It is recommended to modify these registers with a load instruction where all the bits, which can be modified only by the hardware, are written with their ‘invariant’ value.

**Bit 15 CTR\_RX:** Correct Transfer for reception

This bit is set by the hardware when an OUT/SETUP transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in USB\_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated. The type of occurred transaction, OUT or SETUP, can be determined from the SETUP bit described below.

A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.

This bit is read/write but only '0' can be written, writing 1 has no effect.

**Bit 14 DTOG\_RX:** Data Toggle, for reception transfers

If the endpoint is not Isochronous, this bit contains the expected value of the data toggle bit (0=DATA0, 1=DATA1) for the next data packet to be received. Hardware toggles this bit, when the ACK handshake is sent to the USB host, following a data packet reception having a matching data PID value; if the endpoint is defined as a control one, hardware clears this bit at the reception of a SETUP PID addressed to this endpoint.

If the endpoint is using the double-buffering feature this bit is used to support packet buffer swapping too (Refer to [Section 18.4.3: Double-buffered endpoints](#)).

If the endpoint is Isochronous, this bit is used only to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (Refer to [Section 18.4.4: Isochronous transfers](#)). Hardware toggles this bit just after the end of data packet reception, since no handshake is used for isochronous transfers.

This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force specific data toggle/packet buffer usage. When the application software writes '0', the value of DTOG\_RX remains unchanged, while writing '1' makes the bit value toggle. This bit is read/write but it can be only toggled by writing 1.

**Bits 13:12 STAT\_RX [1:0]:** Status bits, for reception transfers

These bits contain information about the endpoint status, which are listed in [Table 68: Reception status encoding on page 419](#). These bits can be toggled by software to initialize their value. When the application software writes '0', the value remains unchanged, while writing '1' makes the bit value toggle. Hardware sets the STAT\_RX bits to NAK when a correct transfer has occurred (CTR\_RX=1) corresponding to a OUT or SETUP (control only) transaction addressed to this endpoint, so the software has the time to elaborate the received data before it acknowledge a new transaction

Double-buffered bulk endpoints implement a special transaction flow control, which control the status based upon buffer availability condition (Refer to [Section 18.4.3: Double-buffered endpoints](#)).

If the endpoint is defined as Isochronous, its status can be only "VALID" or "DISABLED", so that the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STAT\_RX bits to 'STALL' or 'NAK' for an Isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing '1'.

**Bit 11 SETUP:** Setup transaction completed

This bit is read-only and it is set by the hardware when the last completed transaction is a SETUP. This bit changes its value only for control endpoints. It must be examined, in the case of a successful receive transaction (CTR\_RX event), to determine the type of transaction occurred. To protect the interrupt service routine from the changes in SETUP bits due to next incoming tokens, this bit is kept frozen while CTR\_RX bit is at 1; its state changes when CTR\_RX is at 0. This bit is read-only.

**Bits 10:9 EP\_TYPE[1:0]:** Endpoint type

These bits configure the behavior of this endpoint as described in [Table 69: Endpoint type encoding on page 419](#). Endpoint 0 must always be a control endpoint and each USB function must have at least one control endpoint which has address 0, but there may be other control endpoints if required. Only control endpoints handle SETUP transactions, which are ignored by endpoints of other kinds. SETUP transactions cannot be answered with NAK or STALL. If a control endpoint is defined as NAK, the USB peripheral will not answer, simulating a receive error, in the receive direction when a SETUP transaction is received. If the control endpoint is defined as STALL in the receive direction, then the SETUP packet will be accepted anyway, transferring data and issuing the CTR interrupt. The reception of OUT transactions is handled in the normal way, even if the endpoint is a control one.

Bulk and interrupt endpoints have very similar behavior and they differ only in the special feature available using the EP\_KIND configuration bit.

The usage of Isochronous endpoints is explained in [Section 18.4.4: Isochronous transfers](#)

**Bit 8 EP\_KIND:** Endpoint kind

The meaning of this bit depends on the endpoint type configured by the EP\_TYPE bits. [Table 70](#) summarizes the different meanings.

**DBL\_BUF:** This bit is set by the software to enable the double-buffering feature for this bulk endpoint. The usage of double-buffered bulk endpoints is explained in [Section 18.4.3: Double-buffered endpoints](#).

**STATUS\_OUT:** This bit is set by the software to indicate that a status out transaction is expected: in this case all OUT transactions containing more than zero data bytes are answered 'STALL' instead of 'ACK'. This bit may be used to improve the robustness of the application to protocol errors during control transfers and its usage is intended for control endpoints only. When STATUS\_OUT is reset, OUT transactions can have any number of bytes, as required.

**Bit 7 CTR\_TX:** Correct Transfer for transmission

This bit is set by the hardware when an IN transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in the USB\_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated.

A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.

This bit is read/write but only '0' can be written.

**Bit 6 DTOG\_TX:** Data Toggle, for transmission transfers

If the endpoint is non-isochronous, this bit contains the required value of the data toggle bit (0=DATA0, 1=DATA1) for the next data packet to be transmitted. Hardware toggles this bit when the ACK handshake is received from the USB host, following a data packet transmission. If the endpoint is defined as a control one, hardware sets this bit to 1 at the reception of a SETUP PID addressed to this endpoint.

If the endpoint is using the double buffer feature, this bit is used to support packet buffer swapping too (Refer to [Section 18.4.3: Double-buffered endpoints](#))

If the endpoint is Isochronous, this bit is used to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (Refer to [Section 18.4.4: Isochronous transfers](#)). Hardware toggles this bit just after the end of data packet transmission, since no handshake is used for Isochronous transfers.

This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force a specific data toggle/packet buffer usage. When the application software writes '0, the value of DTOG\_TX remains unchanged, while writing '1 makes the bit value toggle. This bit is read/write but it can only be toggled by writing 1.

Bits 5:4 **STAT\_TX [1:0]**: Status bits, for transmission transfers

These bits contain the information about the endpoint status, listed in [Table 71](#). These bits can be toggled by the software to initialize their value. When the application software writes '0, the value remains unchanged, while writing '1 makes the bit value toggle. Hardware sets the STAT\_TX bits to NAK, when a correct transfer has occurred (CTR\_TX=1) corresponding to a IN or SETUP (control only) transaction addressed to this endpoint. It then waits for the software to prepare the next set of data to be transmitted.

Double-buffered bulk endpoints implement a special transaction flow control, which controls the status based on buffer availability condition (Refer to [Section 18.4.3: Double-buffered endpoints](#)).

If the endpoint is defined as Isochronous, its status can only be "VALID" or "DISABLED".

Therefore, the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STAT\_TX bits to 'STALL' or 'NAK' for an Isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing '1.

Bits 3:0 **EA[3:0]**: Endpoint address

Software must write in this field the 4-bit address used to identify the transactions directed to this endpoint. A value must be written before enabling the corresponding endpoint.

**Table 68. Reception status encoding**

STAT_RX[1:0]	Meaning
00	<b>DISABLED</b> : all reception requests addressed to this endpoint are ignored.
01	<b>STALL</b> : the endpoint is stalled and all reception requests result in a STALL handshake.
10	<b>NAK</b> : the endpoint is naked and all reception requests result in a NAK handshake.
11	<b>VALID</b> : this endpoint is enabled for reception.

**Table 69. Endpoint type encoding**

EP_TYPE[1:0]	Meaning
00	BULK
01	CONTROL
10	ISO
11	INTERRUPT

**Table 70. Endpoint kind meaning**

EP_TYPE[1:0]		EP_KIND Meaning
00	BULK	DBL_BUF
01	CONTROL	STATUS_OUT
10	ISO	Not used
11	INTERRUPT	Not used

**Table 71. Transmission status encoding**

STAT_TX[1:0]	Meaning
00	<b>DISABLED:</b> all transmission requests addressed to this endpoint are ignored.
01	<b>STALL:</b> the endpoint is stalled and all transmission requests result in a STALL handshake.
10	<b>NAK:</b> the endpoint is naked and all transmission requests result in a NAK handshake.
11	<b>VALID:</b> this endpoint is enabled for transmission.

### 18.5.3 Buffer descriptor table

Although the buffer descriptor table is located inside the packet buffer memory, its entries can be considered as additional registers used to configure the location and size of the packet buffers used to exchange data between the USB macro cell and the STM32L15xxx. Due to the common APB bridge limitation on word addressability, all packet memory locations are accessed by the APB using 32-bit aligned addresses, instead of the actual memory location addresses utilized by the USB peripheral for the USB\_BTABLE register and buffer description table locations.

In the following pages two location addresses are reported: the one to be used by application software while accessing the packet memory, and the local one relative to USB Peripheral access. To obtain the correct STM32L15xxx memory address value to be used in the application software while accessing the packet memory, the actual memory location address must be multiplied by two. The first packet memory location is located at 0x4000 6000. The buffer descriptor table entry associated with the USB\_EPnR registers is described below.

A thorough explanation of packet buffers and the buffer descriptor table usage can be found in [Structure and usage of packet buffers on page 397](#).

#### Transmission buffer address n (USB\_ADDRn\_TX)

Address offset: [USB\_BTABLE] + n\*16

USB local address: [USB\_BTABLE] + n\*8

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRn_TX[15:1]															-
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	-

Bits 15:1 **ADDRn\_TX[15:1]:** Transmission buffer address

These bits point to the starting address of the packet buffer containing data to be transmitted by the endpoint associated with the USB\_EPnR register at the next IN token addressed to it.

Bit 0 Must always be written as '0 since packet memory is word-wide and all packet buffers must be word-aligned.

**Transmission byte count n (USB\_COUNTn\_TX)**

Address offset: [USB\_BTABLE] + n\*16 + 4

USB local Address: [USB\_BTABLE] + n\*8 + 2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						COUNTn_TX[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:10 These bits are not used since packet size is limited by USB specifications to 1023 bytes. Their value is not considered by the USB peripheral.

Bits 9:0 **COUNTn\_TX[9:0]**: Transmission byte count

These bits contain the number of bytes to be transmitted by the endpoint associated with the USB\_EPnR register at the next IN token addressed to it.

*Note: Double-buffered and Isochronous IN Endpoints have two USB\_COUNTn\_TX registers: named USB\_COUNTn\_TX\_1 and USB\_COUNTn\_TX\_0 with the following content.*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved						COUNTn_TX_1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						COUNTn_TX_0[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

**Reception buffer address n (USB\_ADDRn\_RX)**

Address offset: [USB\_BTABLE] + n\*16 + 8

USB local Address: [USB\_BTABLE] + n\*8 + 4

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRn_RX[15:1]															-
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	-

Bits 15:1 **ADDRn\_RX[15:1]**: Reception buffer address

These bits point to the starting address of the packet buffer, which will contain the data received by the endpoint associated with the USB\_EPnR register at the next OUT/SETUP token addressed to it.

Bit 0 This bit must always be written as '0 since packet memory is word-wide and all packet buffers must be word-aligned.

**Reception byte count n (USB\_COUNTn\_RX)**

Address offset: [USB\_BTABLE] + n\*16 + 12

USB local Address: [USB\_BTABLE] + n\*8 + 6

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLSIZE	NUM_BLOCK[4:0]					COUNTn_RX[9:0]									
rw	rw	rw	rw	rw	rw	r	r	r	r	r	r	r	r	r	r

This table location is used to store two different values, both required during packet reception. The most significant bits contains the definition of allocated buffer size, to allow buffer overflow detection, while the least significant part of this location is written back by the USB peripheral at the end of reception to give the actual number of received bytes. Due to the restrictions on the number of available bits, buffer size is represented using the number of allocated memory blocks, where block size can be selected to choose the trade-off between fine-granularity/small-buffer and coarse-granularity/large-buffer. The size of allocated buffer is a part of the endpoint descriptor and it is normally defined during the enumeration process according to its maxPacketSize parameter value (See “Universal Serial Bus Specification”).

**Bit 15 BL\_SIZE:** BLock size

This bit selects the size of memory block used to define the allocated buffer area.

- If BL\_SIZE=0, the memory block is 2 byte large, which is the minimum block allowed in a word-wide memory. With this block size the allocated buffer size ranges from 2 to 62 bytes.
- If BL\_SIZE=1, the memory block is 32 byte large, which allows to reach the maximum packet length defined by USB specifications. With this block size the allocated buffer size ranges from 32 to 1024 bytes, which is the longest packet size allowed by USB standard specifications.

**Bits 14:10 NUM\_BLOCK[4:0]:** Number of blocks

These bits define the number of memory blocks allocated to this packet buffer. The actual amount of allocated memory depends on the BL\_SIZE value as illustrated in [Table 72](#).

**Bits 9:0 COUNTn\_RX[9:0]:** Reception byte count

These bits contain the number of bytes received by the endpoint associated with the USB\_EPnR register during the last OUT/SETUP transaction addressed to it.

*Note: Double-buffered and Isochronous IN Endpoints have two USB\_COUNTn\_TX registers: named USB\_COUNTn\_TX\_1 and USB\_COUNTn\_TX\_0 with the following content.*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BLSIZE_1	NUM_BLOCK_1[4:0]					COUNTn_RX_1[9:0]									
rw	rw	rw	rw	rw	rw	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLSIZE_0	NUM_BLOCK_0[4:0]					COUNTn_RX_0[9:0]									
rw	rw	rw	rw	rw	rw	r	r	r	r	r	r	r	r	r	r

**Table 72. Definition of allocated buffer memory**

Value of NUM_BLOCK[4:0]	Memory allocated when BL_SIZE=0	Memory allocated when BL_SIZE=1
0 ('00000)	Not allowed	32 bytes
1 ('00001)	2 bytes	64 bytes
2 ('00010)	4 bytes	96 bytes
3 ('00011)	6 bytes	128 bytes
...	...	...
15 ('01111)	30 bytes	512 bytes
16 ('10000)	32 bytes	N/A
17 ('10001)	34 bytes	N/A
18 ('10010)	36 bytes	N/A
...	...	...
30 ('11110)	60 bytes	N/A
31 ('11111)	62 bytes	N/A

### 18.5.4 USB register map

The table below provides the USB register map and reset values.

**Table 73. USB register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Note: Refer to Table 1 on page 32 for the register boundary addresses.

## 19 CRC calculation unit

This section applies to the whole STM32L15xxx family, unless otherwise specified.

### 19.1 CRC introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from a 32-bit data word and a fixed generator polynomial.

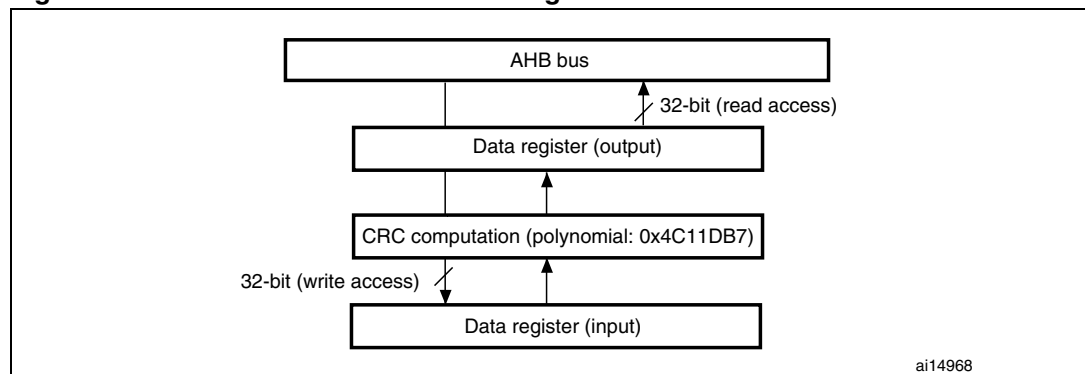

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the EN/IEC 60335-1 standard, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link-time and stored at a given memory location.

### 19.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  - $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Single input/output 32-bit data register
- CRC computation done in 4 AHB clock cycles (HCLK)
- General-purpose 8-bit register (can be used for temporary storage)

The block diagram is shown in [Figure 158](#).

**Figure 158. CRC calculation unit block diagram**

### 19.3 CRC functional description

The CRC calculation unit mainly consists of a single 32-bit data register, which:

- is used as an input register to enter new data in the CRC calculator (when writing into the register)
- holds the result of the previous CRC calculation (when reading the register)

Each write operation into the data register creates a combination of the previous CRC value and the new one (CRC computation is done on the whole 32-bit data word, and not byte per byte).

The write operation is stalled until the end of the CRC computation, thus allowing back-to-back write accesses or consecutive write and read accesses.

The CRC calculator can be reset to FFFF FFFFh with the RESET control bit in the CRC\_CR register. This operation does not affect the contents of the CRC\_IDR register.

## 19.4 CRC registers

The CRC calculation unit contains two data registers and a control register.

### 19.4.1 Data register (CRC\_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

Bits 31:0 **Data register bits**

Used as an input register when writing new data into the CRC calculator.  
 Holds the previous CRC calculation result when it is read.

### 19.4.2 Independent data register (CRC\_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

Bits 31:8 Reserved

Bits 7:0 **General-purpose 8-bit data register bits**

Can be used as a temporary storage location for one byte.  
 This register is not affected by CRC resets generated by the RESET bit in the CRC\_CR register.

### 19.4.3 Control register (CRC\_CR)

Address offset: 0x08

Reset value: 0x0000 0000

Bits 31:1 **Reserved**

Bit 0 **RESET bit**

Resets the CRC calculation unit and sets the data register to FFFF FFFFh.  
This bit can only be set, it is automatically cleared by hardware.

### 19.4.4 CRC register map

The following table provides the CRC register map and reset values.

**Table 74. CRC calculation unit register map and reset values**

Offset	Register	31-24	23-16	15-8	7	6	5	4	3	2	1	0	
0x00	<b>CRC_DR</b> Reset value	Data register 0xFFFF FFFF											
0x04	<b>CRC_IDR</b> Reset value	Reserved			Independent data register 0x00								
0x08	<b>CRC_CR</b> Reset value	Reserved											RESET 0

## 20 Real-time clock (RTC)

### 20.1 Introduction

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar, two programmable alarm interrupts, and a periodic programmable wakeup flag with interrupt capability. The RTC also includes an automatic wakeup unit to manage low power modes.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD).

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm seconds, minutes, hours, day, and date.

After power-on reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low power mode or under reset).

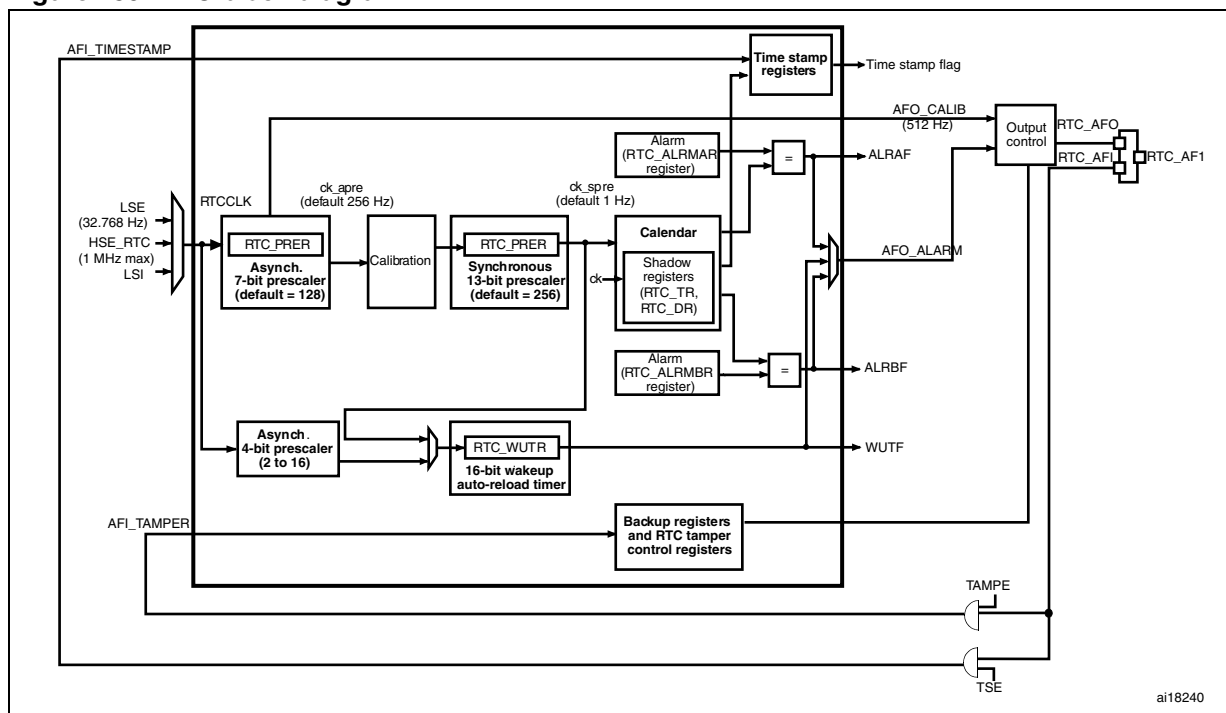

## 20.2 RTC main features

The RTC unit main features are the following (see [Figure 159: RTC block diagram](#)):

- Calendar with seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Two programmable alarms with interrupt function. The alarms can be triggered by any combination of the calendar fields.
- Automatic wakeup unit generating a periodic flag that triggers an automatic wakeup interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Maskable interrupts/events:
  - Alarm A
  - Alarm B
  - Wakeup interrupt
  - Time-stamp
  - Tamper detection
- Digital calibration circuit (periodic counter correction)
  - 5 ppm accuracy
- Time-stamp function for event saving (1 event)
- Tamper detection:
  - 1 tamper event on edge detection
- 20 backup registers (80 bytes). The backup registers are reset when a tamper detection event occurs.
- RTC alternate function outputs (RTC\_AFO):
  - AFO\_CALIB: 512 Hz clock output (with an LSE frequency of 32.768 kHz). It is routed to the device RTC\_AF1 pin.
  - AFO\_ALARM: Alarm A or Alarm B or wakeup (only one can be selected). It is routed to the device RTC\_AF1 pin.
- RTC alternate function inputs (RTC\_AFI):
  - AFI\_TAMPER: tamper event detection. It is routed to the device RTC\_AF1 pin.
  - AFI\_TIMESTAMP: timestamp event detection. It is routed to the device RTC\_AF1 pin.

*Note:* Refer to [Section 5.3.15: Selection of RTC\\_AF1 alternate functions](#) for more details on how to select RTC alternate functions (RTC\_AF1).

Figure 159. RTC block diagram

## 20.3 RTC functional description

### 20.3.1 Clock and prescalers

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to [Section 4: Reset and clock control \(RCC\)](#).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see [Figure 159.: RTC block diagram](#)):

- A 7-bit asynchronous prescaler configured through the PREDIV\_A bits of the RTC\_PRER register.
- A 13-bit synchronous prescaler configured through the PREDIV\_S bits of the RTC\_PRER register.

*Note:* When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck\_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 2 and the maximum division factor is  $2^{20}$ .

This corresponds to a maximum input frequency of around 1 MHz.

$f_{\text{ck\_spre}}$  is given by the following formula:

$$f_{\text{CK\_SPRE}} = \frac{f_{\text{RTCCLK}}}{(\text{PREDIV\_S} + 1) \times (\text{PREVID\_A} + 1)}$$

The ck\_spre clock can be used either to update the calendar or as timebase for the 16-bit wakeup auto-reload timer. To obtain short timeout periods, the 16-bit wakeup auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see [Section 20.3.4: Periodic auto-wakeup](#) for details).

### 20.3.2 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK1 (APB1 clock):

- RTC\_TR for the time
- RTC\_DR for the date

Every two RTCCLK periods, the current calendar value is copied into the shadow registers, and the RSF bit of RTC\_ISR register is set (see [Section 20.6.4](#)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 2 RTCCLK periods.

When the application reads the calendar registers, it accesses the content of the shadow registers.

When reading the RTC\_TR or RTC\_DR registers, the frequency of the APB clock ( $f_{\text{APB}}$ ) must be at least 7 times the frequency of the RTC clock ( $f_{\text{RTCCLK}}$ ).

The shadow registers are reset by system reset.

### 20.3.3 Programmable alarms

The RTC unit provides **two** programmable alarms, Alarm A and Alarm B.

The programmable alarm functions are enabled through the ALRAE and ALRBE bits in the RTC\_CR register. The ALRAF and ALRBF flags are set to 1 if the calendar seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC\_ALRMAR and RTC\_ALRMBR, respectively. Each calendar field can be independently selected through the MSKx bits of the RTC\_ALRMAR and RTC\_ALRMBR registers. The alarm interrupts are enabled through the ALRAIE and ALRBE bits in the RTC\_CR register.

Alarm A and Alarm B (if enabled by bits OSEL[0:1] in RTC\_CR register) can be routed to the AFO\_ALARM output. AFO\_ALARM polarity can be configured through bit POL the RTC\_CR register.

**Caution:** If the seconds field is selected (MSK0 bit reset in RTC\_ALRMAR or RTC\_ALRMBR), the synchronous prescaler division factor set in the RTC\_PRER register must be at least 3 to ensure correct behavior.

### 20.3.4 Periodic auto-wakeup

The periodic wakeup flag is generated by a 16-bit programmable auto-reload down-counter. The wakeup timer range can be extended to 17 bits.

The wakeup function is enabled through the WUTE bit in the RTC\_CR register.

The wakeup timer clock input can be :

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.  
When RTCCLK is LSE(32.768kHz), this allows to configure the wakeup interrupt period from 122  $\mu$ s to 32 s, with a resolution down to 61 $\mu$ s .
- ck\_spre (usually 1 Hz internal clock)  
When ck\_spre frequency is 1Hz, this allows to achieve a wakeup time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1s to 18 hours when WUCKSEL [2:1] = 10
  - and from around 18h to 36h when WUCKSEL[2:1] = 11. In this last case 2<sup>16</sup> is added to the 16-bit counter current value. When the initialization sequence is complete (see [Programming the wakeup timer on page 434](#)), the timer starts counting down. When the wakeup function is enabled, the down-counting remains active in low power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC\_ISR register, and the wakeup counter is automatically reloaded with its reload value (RTC\_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wakeup interrupt is enabled by setting the WUTIE bit in the RTC\_CR2 register, it can exit the device from low power modes.

The periodic wakeup flag can be routed to the AFO\_ALARM output provided it has been enabled through bits OSEL[0:1] of RTC\_CR register. AFO\_ALARM polarity can be configured through the POLbit in the RTC\_CR register.

System reset, as well as low power modes (Sleep, Stop and Standby) have no influence on the wakeup timer.

### 20.3.5 RTC initialization and configuration

#### RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses .

#### RTC register write protection

After power-on reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC\_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC\_ISR[13:8], RTC\_TAFCR, and RTC\_BKPxR.

1. Write '0xCA' into the RTC\_WPR register.
2. Write '0x53' into the RTC\_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

## Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC\_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC\_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program first the synchronous prescaler factor in RTC\_PRER register, and then program the asynchronous prescaler factor. Even if only one of the two fields needs to be changed, 2 separate write accesses must be performed to the TC\_PRER register.
4. Load the initial time and date values in the shadow registers (RTC\_TR and RTC\_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC\_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

- Note:*
- 1 After a system reset, the application can read the INITS flag in the RTC\_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its power-on reset default value (0x00).
  - 2 To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC\_ISR register.

## Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC\_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

## Programming the alarm

A similar procedure must be followed to program or update the programmable alarms (Alarm A or Alarm B):

1. Clear ALRAE or ALRBE in RTC\_CR to disable Alarm A or Alarm B.
2. Poll ALRAWF or ALRBWF in RTC\_ISR until it is set to make sure the access to alarm registers is allowed. This takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the Alarm A or Alarm B registers (RTC\_ALRMAR or /RTC\_ALRMBR).
4. Set ALRAE or ALRBE in the RTC\_CR register to enable Alarm A or Alarm B again.

- Note:* Each change of the RTC\_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

### Programming the wakeup timer

The following sequence is required to configure or change the wakeup timer auto-reload value (WUT[15:0] in RTC\_WUTR):

1. Clear WUTE in RTC\_CR to disable the wakeup timer.
2. Poll WUTWF until it is set in RTC\_ISR to make sure the access to wakeup auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wakeup auto-reload value WUT[15:0], and the wakeup clock selection (WUCKSEL[2:0] bits in RTC\_CR). Set WUTE in RTC\_CR to enable the timer again. The wakeup timer restarts down-counting.

### 20.3.6 Reading the calendar

To read the RTC calendar registers (RTC\_TR and RTC\_DR) properly, the APB1 clock frequency ( $f_{PCLK1}$ ) must be equal to or greater than seven times the  $f_{RTCCLK}$  RTC clock frequency. This ensures a secure behavior of the synchronization mechanism.

If the APB1 clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB1 clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC\_ISR register each time the calendar registers are copied into the RTC\_TR and RTC\_DR shadow registers. The copy is performed every two RTCCLK cycles. To ensure consistency between the 2 values, reading RTC\_TR locks the values in the higher-order calendar shadow registers until RTC\_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 2 RTCCLK periods: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC\_TR and RTC\_DR registers.

After waking up from low power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC\_TR and RTC\_DR registers.

The RSF bit must be cleared after wakeup and not before entering low power mode.

- Note:*
- 1 After a system reset, the software must wait until RSF is set before reading the RTC\_TR and RTC\_DR registers. Indeed, a system reset resets the shadow registers to their default values.
  - 2 After an initialization (refer to [Section : Calendar initialization and configuration](#)): the software must wait until RSF is set before reading the RTC\_TR and RTC\_DR registers.

### 20.3.7 Resetting the RTC

The calendar shadow registers (RTC\_TR and RTC\_DR) and the RTC status register (RTC\_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a power-on reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC\_CR), the prescaler register (RTC\_PRER), the RTC calibration registers (RTC\_CALIBR), the RTC timestamp registers (RTC\_TSTR and RTC\_TSDR), the RTC tamper and alternate function configuration register (RTC\_TAFCR), the RTC backup

registers (RTC\_BKPxR), the wakeup timer register (RTC\_WUTR), the Alarm A and Alarm B registers (RTC\_ALRMAR and RTC\_ALRMBR).

In addition, the RTC keeps on running under system reset if the reset source is different from the power-on reset one. When a power-on reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

### 20.3.8 RTC reference clock detection

The reference clock (at 50 Hz or 60 Hz) should have a higher precision than the 32.768 kHz LSE clock. When the reference clock detection is enabled (REFCKON bit of RTC\_CR set to 1), it is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest reference clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

If the reference clock halts, the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a detection window centered on the ck\_spre edge.

When the reference clock detection is enabled, PREDIV\_A and PREDIV\_S must be set to their default values:

- PREDIV\_A = 0x007F
- PREDIV\_S = 0x00FF

### 20.3.9 RTC digital calibration

The digital calibration can be used to achieve a 5 ppm accuracy by adding (positive calibration) or masking (negative calibration) clock cycles at the output of the asynchronous prescaler (ck\_apre).

Positive and negative calibration are selected by setting the DCS bit in RTC\_CALIBR register to '0' and '1', respectively.

When positive calibration is enabled (DCS = '0'), 2 ck\_apre cycles are added every minute (around 15360 ck\_apre cycles) for 2xDC minutes. This causes the calendar to be updated sooner, thereby adjusting the effective RTC frequency to be a bit higher.

When negative calibration is enabled (DCS = '1'), 1 ck\_apre cycle is removed every minute (around 15360 ck\_apre cycles) for 2xDC minutes. This causes the calendar to be updated later, thereby adjusting the effective RTC frequency to be a bit lower.

DC is configured through bits DC[4:0] of RTC\_CALIBR register. This number ranges from 0 to 31 corresponding to a time interval (2xDC) ranging from 0 to 62.

The digital calibration can be configured only in initialization mode, and starts when the INIT bit is cleared. The full calibration cycle lasts 64 minutes. The first 2xDC minutes of the 64 - minutecycle are modified as just described.

Negative calibration can be performed with a resolution of about 2 ppm while positive calibration can be performed with a resolution of about 4 ppm. The maximum calibration ranges from -63 ppm to 126 ppm.

The calibration can be performed either on the LSE or on the HSE clock.

**Caution:** Digital calibration may not work correctly if  $PREDIV\_A < 6$ .

### Case of $RTCCLK=32.768$ kHz and $PREDIV\_A+1=128$

The following description assumes that  $ck\_apre$  frequency is 256 Hz obtained with an LSE clock nominal frequency of 32.768 kHz, and  $PREDIV\_A$  set to 127 (default value).

The  $ck\_spre$  clock frequency is only modified during the first 2xDC minutes of the 64-minute cycle. For example, when DC equals 1, only the first 2 minutes are modified. This means that the first 2xDC minutes of each 64-minute cycle have, once per minute, one second either shortened by 256 or lengthened by 128 RTCCLK cycles, given that each  $ck\_apre$  cycle represents 128 RTCCLK cycles (with  $PREDIV\_A+1=128$ ).

Therefore each calibration step has the effect of adding 512 or subtracting 256 oscillator cycles for every 125829120 RTCCLK cycles (64min x 60 s/min x 32768 cycles/s). This is equivalent to +4.069 ppm or -2.035 ppm per calibration step. As a result, the calibration resolution is +10.5 or -5.27 seconds per month, and the total calibration ranges from +5.45 to -2.72 minutes per month.

In order to measure the clock deviation, a 512 Hz clock is output for calibration. Refer to [Section 20.3.12: Calibration clock output](#).

## 20.3.10 Time-stamp function

Time-stamp is enabled by setting the TSE bit of RTC\_CR register to 1.

The calendar is saved in the time-stamp registers (RTC\_TSTR, RTC\_TSDR) when a time-stamp event is detected on the pin to which the TIMESTAMP alternate function is mapped. When a time-stamp event occurs, the time-stamp flag bit (TSF) in RTC\_ISR register is set.

By setting the TSIE bit in the RTC\_CR register, an interrupt is generated when a time-stamp event occurs.

If a new time-stamp event is detected while the time-stamp flag (TSF) is already set, the TSOVF flag is set and the time-stamp registers (RTC\_TSTR and RTC\_TSDR) maintain the results of the previous event.

- Note:*
- 1 *TSF is set 2  $ck\_apre$  cycles after the time-stamp event occurs due to synchronization process.*
  - 2 *There is no delay in the setting of TSOVF. This means that if two time-stamp events are close together, TSOVF can be seen as '1' while TSF is still '0'. As a consequence, it is recommended to poll TSOVF only after TSF has been set.*

**Caution:** If a time-stamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a time-stamp event occurring at the same moment, the application must not write '0' into TSF bit unless it has already read it to '1'.

### TIMESTAMP alternate function

The TIMESTAMP alternate function is mapped to RTC\_AF1.

## 20.3.11 Tamper detection

### RTC backup registers

The backup registers (RTC\_BKPxR) are twenty 32-bit registers for storing 80bytes of user application data. They are implemented in the  $V_{DD}$  domain . They are not reset by system reset, or when the device wakes up from Standby mode. They are reset by a power-on reset.

The backup registers are reset when a tamper detection event occurs (see [Section 20.6.14: RTC backup registers \(RTC\\_BKPxR\)](#) and [Section : Tamper detection initialization](#)).

### Tamper detection initialization

The tamper detection input is associated with a flag TAMP1F in the RTC\_ISR2 register. The input can be enabled by setting the TAMP1E bit to 1 in the RTC\_TAFCR register.

A tamper detection event resets all backup registers (RTC\_BKPxR).

By setting the TAMPIE bit in the RTC\_TAFCR register, an interrupt is generated when a tamper detection event occurs.

### Edge detection on tamper inputs:

TAMPER pins generate tamper detection events when either a rising edge is observed or an falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the TAMPER inputs are deactivated when edge detection is selected.

**Caution:** To avoid losing tamper detection events, the signal used for edge detection is logically ANDed with TAMPxE in order to detect a tamper detection event in case it occurs before the TAMPERx pin is enabled.

- When TAMPxTRG = 0: if the TAMPERx alternate function is already high before tamper detection is enabled (TAMPxE bit set to 1), a tamper event is detected as soon as TAMPERx is enabled, even if there was no rising edge on TAMPERx after TAMPxE was set.
- When TAMPxTRG = 1: if the TAMPERx alternate function is already low before tamper detection is enabled, a tamper event is detected as soon as TAMPERx is enabled (even if there was no falling edge on TAMPERx after TAMPxE was set).

After a tamper event has been detected and cleared, the TAMPERx alternate function should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (RTC\_BKPxR). This prevents the application from writing to the backup registers while the TAMPERx value still indicates a tamper detection. This is equivalent to a level detection on the TAMPERx alternate function.

**Note:** *Tamper detection is still active when  $V_{DD}$  power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the TAMPER alternate function is mapped should be externally tied to the correct level.*

### TAMPER alternate function detection

The TAMPER1 alternate function is mapped to the RTC\_AF1 pin.

### 20.3.12 Calibration clock output

When the COE bit is set to 1 in the RTC\_CR register, a reference clock is provided on the RTC\_CALIB device output. If PREDIV\_A = 0x7F, the RTC\_CALIB frequency is  $f_{\text{RTCCLK}}/64$ . This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz.

The RTC\_CALIB output is not impacted by the calibration value programmed in RTC\_CALIBR register. The RTC\_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

#### Calibration alternate function output

When the COE bit in the RTC\_CR register is set to 1, the calibration alternate function (AFO\_CALIB) is enabled on RTC\_AF1.

### 20.3.13 Alarm output

Three functions can be selected on Alarm output: ALRAF, ALRBF and WUTF. These functions reflect the contents of the corresponding flags in the RTC\_ISR register.

The OSEL[1:0] control bits in the RTC\_CR register are used to activate the alarm alternate function output (AFO\_ALARM) in RTC\_AF1, and to select the function which is output on AFO\_ALARM.

The polarity of the output is determined by the POL control bit in RTC\_CR so that the opposite of the selected flag bit is output when POL is set to 1.

#### Alarm alternate function output

AFO\_ALARM can be configured in output open drain or output push-pull using the control bit ALARMOUTTYPE in the RTC\_TAFPCR register.

- Note:*
- 1 the AFO\_CALIB should be disabled (COE bit must be kept cleared).
  - 2 When AFO\_CALIB or AFO\_ALARM is selected, RTC\_AF1 is automatically configured in output alternate function.

## 20.4 RTC and low power modes

**Table 75. Effect of low power modes on RTC**

Mode	Description
Sleep	No effect RTC interrupts cause the device to exit the Sleep mode.
Stop	The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC time stamp event, and RTC Wakeup cause the device to exit the Stop mode.
Standby	The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC time stamp event, and RTC Wakeup cause the device to exit the Standby mode.

## 20.5 RTC interrupts

All RTC interrupts are connected to the EXTI controller.

To enable the RTC Alarm interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 17 in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC\_Alarm IRQ channel in the NVIC.
3. Configure the RTC to generate RTC alarms (Alarm A or Alarm B).

To enable the RTC Wakeup interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 20 in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC\_WKUP IRQ channel in the NVIC.
3. Configure the RTC to generate the RTC wakeup timer event.

To enable the RTC Tamper interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 19 in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC tamper event.

To enable the RTC TimeStamp interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 19 in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC time-stamp event.

**Table 76. Interrupt control bits**

Interrupt event	Event flag	Enable control bit	Exit the Sleep mode	Exit the Stop mode	Exit the Standby mode
Alarm A	ALRAF	ALRAIE	yes	yes <sup>(1)</sup>	yes <sup>(1)</sup>
Alarm B	ALRBF	ALRBIE	yes	yes <sup>(1)</sup>	yes <sup>(1)</sup>
Wakeup	WUTF	WUTIE	yes	yes <sup>(1)</sup>	yes <sup>(1)</sup>
TimeStamp	TSF	TSIE	yes	yes <sup>(1)</sup>	yes <sup>(1)</sup>
Tamper1 detection	TAMP1F	TAMPIE	yes	yes <sup>(1)</sup>	yes <sup>(1)</sup>

1. Wakeup from STOP and Standby modes is possible only when the RTC clock source is LSE or LSI.

## 20.6 RTC registers

Refer to [Section 1.1](#) of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

### 20.6.1 RTC time register (RTC\_TR)

The RTC\_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 433](#) and [Reading the calendar on page 434](#).

Address offset: 0x00

Power-on reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									PM	HT[1:0]		HU[3:0]			
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserv ed	MNT[2:0]			MNU[3:0]				Reserv ed	ST[2:0]			SU[3:0]			
	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31-24 Reserved

Bit 23 Reserved, always read as 0.

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bit 16:16 **HU[3:0]**: Hour units in BCD format

Bit 15 Reserved, always read as 0.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bit 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 Reserved, always read as 0.

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bit 3:0 **SU[3:0]**: Second units in BCD format

*Note:* This register is write protected. The write access procedure is described in [RTC register write protection on page 432](#).

### 20.6.2 RTC date register (RTC\_DR)

The RTC\_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 433](#) and [Reading the calendar on page 434](#).

Address offset: 0x04

Power-on reset value: 0x0000 2101

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								YT[3:0]				YU[3:0]			
								rw	rw	rw	rw	rw	rw	rw	rw

WDU[2:0]			MT	MU[3:0]				Reserved		DT[1:0]		DU[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31-24 Reserved

Bits 23:20 **YT[3:0]**: Year tens in BCD format

Bits 19:16 **YU[3:0]**: Year units in BCD format

Bits 15:13 **WDU[2:0]**: Week day units

000: forbidden

001: Monday

...

111: Sunday

Bit 12 **MT**: Month tens in BCD format

Bits 11:8 **MU**: Month units in BCD format

Bits 7:6 Reserved, always read as 0.

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bits 3:0 **DU[3:0]**: Date units in BCD format

*Note:* This register is write protected. The write access procedure is described in [RTC register write protection on page 432](#).

### 20.6.3 RTC control register (RTC\_CR)

Address offset: 0x08

Power-on value: 0x0000 0000

Reset value: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								COE	OSEL[1:0]		POL	Reserv- ed	BKP	SUB1H	ADD1H
								rw	rw	rw	rw		rw	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSIE	WUTIE	ALRBIE	ALRAIE	TSE	WUTE	ALRBE	ALRAE	DCE	FMT	Reser- ved	REFCKON	TSEDGE	WUCKSEL[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:24 Reserved, always read as 0.

Bit 23 **COE**: Calibration output enable

This bit enables the AFO\_CALIB RTC output

0: Calibration output disabled

1: Calibration output enabled

Bits 22:21 **OSEL[1:0]**: Output selection

These bits are used to select the flag to be routed to AFO\_ALARM RTC output

00: Output disabled

01: Alarm A output enabled

10: Alarm B output enabled

11: Wakeup output enabled

Bit 20 **POL**: Output polarity

This bit is used to configure the polarity of AFO\_ALARM RTC output

0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0])

1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]).

Bit 19 Reserved, always read as 0.

Bit 18 **BKP**: Backup

This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

Bit 17 **SUB1H**: Subtract 1 hour (winter time change)

When this bit is set outside initialization mode, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.

Setting this bit has no effect when current hour is 0.

0: No effect

1: Subtracts 1 hour to the current time. This can be used for winter time change.

Bit 16 **ADD1H**: Add 1 hour (summer time change)

When this bit is set outside initialization mode, 1 hour is added to the calendar time. This bit is always read as 0.

0: No effect

1: Adds 1 hour to the current time. This can be used for summer time change

Bit 15 **TSIE**: Time-stamp interrupt enable

0: Time-stamp Interrupt disable

1: Time-stamp Interrupt enable

- Bit 14 **WUTIE**: Wakeup timer interrupt enable  
0: Wakeup timer interrupt disabled  
1: Wakeup timer interrupt enabled
- Bit 13 **ALRBIE**: Alarm B interrupt enable  
0: Alarm B Interrupt disable  
1: Alarm B Interrupt enable
- Bit 12 **ALRAIE**: Alarm A interrupt enable  
0: Alarm A interrupt disabled  
1: Alarm A interrupt enabled
- Bit 11 **TSE**: Time stamp enable  
0: Time stamp disable  
1: Time stamp enable
- Bit 10 **WUTE**: Wakeup timer enable  
0: Wakeup timer disabled  
1: Wakeup timer enabled
- Bit 9 **ALRBE**: Alarm B enable  
0: Alarm B disabled  
1: Alarm B enabled
- Bit 8 **ALRAE**: Alarm A enable  
0: Alarm A disabled  
1: Alarm A enabled
- Bit 7 **DCE**: Digital calibration enable  
0: Digital calibration disabled  
1: Digital calibration enabled  
PREDIV\_A must be 6 or greater
- Bit 6 **FMT**: Hour format  
0: 24 hour/day format  
1: AM/PM hour format
- Bit 5 Reserved, always read as 0.
- Bit 4 **REFCKON**: Reference clock detection enable (50 or 60 Hz)  
0: Reference clock detection disabled  
1: Reference clock detection enabled  
*Note: PREDIV\_S must be 0x00FF.*
- Bit 3 **TSEEDGE**: Time-stamp event active edge  
0: TIMESTAMP rising edge generates a time-stamp event  
1: TIMESTAMP falling edge generates a time-stamp event  
TSE must be reset when TSEEDGE is changed to avoid unwanted TSF setting.
- Bits 2:0 **WUCKSEL[2:0]**: Wakeup clock selection  
000: RTC/16 clock is selected  
001: RTC/8 clock is selected  
010: RTC/4 clock is selected  
011: RTC/2 clock is selected  
10x: ck\_spre (usually 1 Hz) clock is selected  
11x: ck\_spre (usually 1 Hz) clock is selected and  $2^{16}$  is added to the WUT counter value  
(see note below)

- Note:
- 1 *WUT = Wakeup unit counter value. WUT = (0x0000 to 0xFFFF) + 0x10000 added when WUCKSEL[2:1 = 11].*
  - 2 *Bits 7, 6 and 4 of this register can be written in initialization mode only (RTC\_ISR/INITF = 1).*
  - 3 *Bits 2 to 0 of this register can be written only when RTC\_CR WUTE bit = 0 and RTC\_ISR WUTWF bit = 1.*
  - 4 *It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.*
  - 5 *ADD1H and SUB1H changes are effective in the next second.*
  - 6 *This register is write protected. The write access procedure is described in [RTC register write protection on page 432](#).*

### 20.6.4 RTC initialization and status register (RTC\_ISR)

Address offset: 0x0C

Reset value: 0x0000 0007

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	TAMP1F	TSOVF	TSF	WUTF	ALRBF	ALRAF	INIT	INITF	RSF	INITS	Res.	WUTWF	ALRBF	ALRAWF
		rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	rw	r	rc_w0	r		r	r	r

Bits 31:14 Reserved

Bit 13 **TAMP1F**: Tamper detection flag

This flag is set by hardware when a tamper detection event is detected.  
It is cleared by software writing 0.

Bit 12 **TSOVF**: Time-stamp overflow flag

This flag is set by hardware when a time-stamp event occurs while TSF is already set.  
This flag is cleared by software by writing 0. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a time-stamp event occurs immediately before the TSF bit is cleared.

Bit 11 **TSF**: Time-stamp flag

This flag is set by hardware when a time-stamp event occurs.  
This flag is cleared by software by writing 0.

Bit 10 **WUTF**: Wakeup timer flag

This flag is set by hardware when the wakeup auto-reload counter reaches 0.  
This flag is cleared by software by writing 0.  
This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 9 **ALRBF**: Alarm B flag

This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm B register (RTC\_ALRMBR).  
This flag is cleared by software by writing 0.

- Bit 8 **ALRAF**: Alarm A flag  
This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm A register (RTC\_ALRMAR).  
This flag is cleared by software by writing 0.
- Bit 7 **INIT**: Initialization mode  
0: Free running mode  
1: Initialization mode used to program time and date register (RTC\_TR and RTC\_DR), and prescaler register (RTC\_PRER). Counters are stopped and start counting from the new value when INIT is reset.
- Bit 6 **INITF**: Initialization flag  
When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.  
0: Calendar registers update is not allowed  
1: Calendar registers update is allowed.
- Bit 5 **RSF**: Registers synchronization flag  
This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC\_TRx, and RTC\_DRx).  
It is cleared either by software or by hardware in initialization mode.  
0: Calendar shadow registers not yet synchronized  
1: Calendar shadow registers synchronized
- Bit 4 **INITS**: Initialization status flag  
This bit is set by hardware when the calendar year field is different from 0 (power-on reset state).  
0: Calendar has not been initialized  
1: Calendar has been initialized
- Bit 3 Reserved, always read as 0.
- Bit 2 **WUTWF**: Wakeup timer write flag  
This bit is set by hardware when the wakeup timer values can be changed, after the WUTE bit has been set to 0 in RTC\_CR.  
0: Wakeup timer configuration update not allowed  
1: Wakeup timer configuration update allowed
- Bit 1 **ALRBWF**: Alarm B write flag  
This bit is set by hardware when Alarm B values can be changed, after the ALRBE bit has been set to 0 in RTC\_CR.  
It is cleared by hardware in initialization mode.  
0: Alarm B update not allowed  
1: Alarm B update allowed.
- Bit 0 **ALRAWF**: Alarm A write flag  
This bit is set by hardware when Alarm A values can be changed, after the ALRAE bit has been set to 0 in RTC\_CR.  
It is cleared by hardware in initialization mode.  
0: Alarm A update not allowed  
1: Alarm A update allowed

- Note:*
- 1 The ALRAF, ALRBF, WUTF and TSF bits are cleared 2 APB clock cycles after programming them to 0.
  - 2 This register is write protected (except for RTC\_ISR[13:8] bits). The write access procedure is described in [RTC register write protection on page 432](#).

### 20.6.5 RTC prescaler register (RTC\_PRER)

Address offset: 0x10

Power-on reset value: 0x007F 00FF

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									PREDIV_A[6:0]						
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			PREDIV_S[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved

Bit 23 Reserved, always read as 0.

Bits 22:16 **PREDIV\_A[6:0]**: Asynchronous prescaler factor

This is the asynchronous division factor:

$$ck\_apre \text{ frequency} = \text{RTCCLK frequency} / (\text{PREDIV\_A} + 1)$$

Note: PREDIV\_A [6:0]= 000000 is forbidden.

Bits 15:13 Reserved, always read as 0.

Bits 12:0 **PREDIV\_S[12:0]**: Synchronous prescaler factor

This is the synchronous division factor:

$$ck\_spre \text{ frequency} = ck\_apre \text{ frequency} / (\text{PREDIV\_S} + 1)$$

- Note:
- 1 This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to [Calendar initialization and configuration on page 433](#)
  - 2 This register is write protected. The write access procedure is described in [RTC register write protection on page 432](#).

### 20.6.6 RTC wakeup timer register (RTC\_WUTR)

Address offset: 0x14

Power-on reset value: 0x0000 FFFF

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved

Bits 15:0 **WUT[15:0]**: Wakeup auto-reload value bits

When the wakeup timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck\_wut cycles. The ck\_wut period is selected through WUCKSEL[2:0] bits of the RTC\_CR register

When WUCKSEL[2] = 1, the wakeup timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

*Note: The first assertion of WUTF occurs (WUT+1) ck\_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.*

- Note:*
- 1 This register can be written only when WUTWF is set to 1 in RTC\_ISR.
  - 2 This register is write protected. The write access procedure is described in [Section : RTC register write protection](#).

### 20.6.7 RTC calibration register (RTC\_CALIBR)

Address offset: 0x18

Power-on reset value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Reserved																
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								DCS	Reserved			DC[4:0]				
								rw				rw	rw	rw	rw	rw

Bits 31:8 Reserved

Bit 7 **DCS**: Digital calibration sign

0: Positive calibration: calendar update frequency is increased

1: Negative calibration: calendar update frequency is decreased

Bits 6:5 Reserved, always read as 0.

Bits 4:0 **DC[4:0]**: Digital calibration  
 DCS = 0 (positive calibration)  
 00000: + 0 ppm  
 00001: + 4 ppm  
 00010: + 8 ppm  
 ..  
 11111: + 126 ppm  
 DCS = 1 (negative calibration)  
 00000: -0 ppm  
 00001: -2 ppm  
 00010: -4 ppm  
 ..  
 11111: -63 ppm

- Note:*
- 1 This register can be written in initialization mode only (*RTC\_ISR/INITF* = '1').
  - 2 This register is write protected. The write access procedure is described in [RTC register write protection on page 432](#).

### 20.6.8 RTC alarm A register (RTC\_ALRMAR)

Address offset: 0x1C  
 Power-on reset value: 0x0000 0000  
 System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSK4	WDSEL	DT[1:0]		DU[3:0]				MSK3	PM	HT[1:0]		HU[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSK2	MNT[2:0]			MNU[3:0]				MSK1	ST[2:0]		SU[3:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

- Bit 31 **MSK4**: Alarm A date mask  
 0: Alarm A set if the date/day match  
 1: Date/day don't care in Alarm A comparison
- Bit 30 **WDSEL**: Week day selection  
 0: DU[3:0] represents the date units  
 1: DU[3:0] represents the week day. DT[1:0] is don't care.
- Bits 29:28 **DT[1:0]**: Date tens in BCD format.
- Bits 27:24 **DU[3:0]**: Date units or day in BCD format.
- Bit 23 **MSK3**: Alarm A hours mask  
 0: Alarm A set if the hours match  
 1: Hours don't care in Alarm A comparison
- Bit 22 **PM**: AM/PM notation  
 0: AM or 24-hour format  
 1: PM
- Bits 21:20 **HT[1:0]**: Hour tens in BCD format.

- Bits 19:16 **HU[3:0]**: Hour units in BCD format.
- Bit 15 **MSK2**: Alarm A minutes mask
  - 0: Alarm A set if the minutes match
  - 1: Minutes don't care in Alarm A comparison
- Bits 14:12 **MNT[2:0]**: Minute tens in BCD format.
- Bits 11:8 **MNU[3:0]**: Minute units in BCD format.
- Bit 7 **MSK1**: Alarm A seconds mask
  - 0: Alarm A set if the seconds match
  - 1: Seconds don't care in Alarm A comparison
- Bits 6:4 **ST[2:0]**: Second tens in BCD format.
- Bits 3:0 **SU[3:0]**: Second units in BCD format.

- Note:
- 1 This register can be written only when *ALRAWF* is set to 1 in *RTC\_ISR*, or in initialization mode.
  - 2 This register is write protected. The write access procedure is described in [RTC register write protection on page 432](#).

### 20.6.9 RTC alarm B register (RTC\_ALRMBR)

Address offset: 0x20  
 Power-on reset value: 0x0000 0000  
 System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSK4	WDSEL	DT[1:0]		DU[3:0]				MSK3	PM	HT[1:0]		HU[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSK2	MNT[2:0]		MNU[3:0]				MSK1	ST[2:0]		SU[3:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

- Bit 31 **MSK4**: Alarm B date mask
  - 0: Alarm B set if the date and day match
  - 1: Date and day don't care in Alarm B comparison
- Bit 30 **WDSEL**: Week day selection
  - 0: DU[3:0] represents the date units
  - 1: DU[3:0] represents the week day. DT[1:0] is don't care.
- Bits 29:28 **DT[1:0]**: Date tens in BCD format
- Bits 27:24 **DU[3:0]**: Date units or day in BCD format
- Bit 23 **MSK3**: Alarm A hours mask
  - 0: Alarm B set if the hours match
  - 1: Hours don't care in Alarm A comparison

- Bit 22 **PM**: AM/PM notation
  - 0: AM or 24-hour format
  - 1: PM
- Bits 21:20 **HT[1:0]**: Hour tens in BCD format
- Bits 19:16 **HU[3:0]**: Hour units in BCD format
  - Bit 15 **MSK2**: Alarm B minutes mask
    - 0: Alarm B set if the minutes match
    - 1: Minutes don't care in Alarm B comparison
- Bits 14:12 **MNT[2:0]**: Minute tens in BCD format
- Bits 11:8 **MNU[3:0]**: Minute units in BCD format
  - Bit 7 **MSK1**: Alarm B seconds mask
    - 0: Alarm B set if the seconds match
    - 1: Seconds don't care in Alarm B comparison
- Bits 6:4 **ST[2:0]**: Second tens in BCD format
- Bits 3:0 **SU[3:0]**: Second units in BCD format

- Note:*
- 1 This register can be written only when ALRBWF is set to 1 in RTC\_ISR, or in initialization mode.
  - 2 This register is write protected. The write access procedure is described in [RTC register write protection on page 432](#).

### 20.6.10 RTC write protection register (RTC\_WPR)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Reserved																
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								KEY								
								w	w	w	w	w	w	w	w	w

Bits 31:8 Reserved, always read as 0.

Bits 7:0 **KEY**: Write protection key

This byte is written by software.

Reading this byte always returns 0x00.

Refer to [Section : RTC register write protection](#) for a description of how to unlock RTC register write protection.

### 20.6.11 RTC time stamp time register (RTC\_TSTR)

Address offset: 0x30

Power-on value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved									PM	HT[1:0]		HU[3:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserv- ed	MNT[2:0]			MNU[3:0]				Reserv- ed	ST[2:0]			SU[3:0]			
	r	r	r	r	r	r	r		r	r	r	r	r	r	r

*Note:* The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

### 20.6.12 RTC time stamp date register (RTC\_TSDR)

Address offset: 0x34

Power-on value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WDU[1:0]			MT	MU[3:0]				Reserved	DT[1:0]		DU[3:0]				
r	r	r	r	r	r	r	r		r	r	r	r	r	r	

Bits 31:16 Reserved, always read as 0.

Bits 15:13 **WDU[1:0]**: Week day units

Bit 12 **MT**: Month tens in BCD format

Bits 11:8 **MU[3:0]**: Month units in BCD format

Bits 7:6 Reserved, always read as 0.

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bit 3:0 **DU[3:0]**: Date units in BCD format

*Note:* The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

### 20.6.13 RTC tamper and alternate function configuration register (RTC\_TAFCR)

Address offset: 0x40

Power-on value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31:19 Reserved. Always read as 0.

Bit 18 **ALARMOUTTYPE**: AFO\_ALARM output type

0: RTC\_AF1 is an open-drain output

1: RTC\_AF1 is a push-pull output

Bit 17:3 Reserved. Always read as 0.

Bit 2 **TAMPIE**: Tamper interrupt enable

0: Tamper interrupt disabled

1: Tamper interrupt enabled

Bit 1 **TAMP1TRG**: Active level for tamper 1

0: TAMPER1 rising edge triggers a tamper detection event.

1: TAMPER1 falling edge triggers a tamper detection event.

Bit 0 **TAMP1E**: Tamper 1 detection enable

0: Tamper 1 detection disabled

1: Tamper 1 detection enabled

### 20.6.14 RTC backup registers (RTC\_BKPxR)

Address offset: 0x50 to 0x9C

Power-on value: 0x0000 0000

System reset: not affected

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BKP[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BKP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w	rw	rw

**Bits 31:0 BKP[31:0]**

The application can write or read data to and from these registers. They are not powered-on when V<sub>DD</sub> is switched off. They are not reset by System reset and their contents remain valid when the device operates in low power mode. This register is reset on a tamper detection event, or when the Flash readout protection is disabled.

### 20.6.15 Register map

## 21 Inter-integrated circuit (I<sup>2</sup>C) interface

### 21.1 I<sup>2</sup>C introduction

I<sup>2</sup>C (inter-integrated circuit) bus Interface serves as an interface between the microcontroller and the serial I<sup>2</sup>C bus. It provides multimaster capability, and controls all I<sup>2</sup>C bus-specific sequencing, protocol, arbitration and timing. It supports standard and fast speed modes. It is also SMBus 2.0 compatible.

It may be used for a variety of purposes, including CRC generation and verification, SMBus (system management bus) and PMBus (power management bus).

Depending on specific device implementation DMA capability can be available for reduced CPU overload.

### 21.2 I<sup>2</sup>C main features

- Parallel-bus/I<sup>2</sup>C protocol converter
- Multimaster capability: the same interface can act as Master or Slave
- I<sup>2</sup>C Master features:
  - Clock generation
  - Start and Stop generation
- I<sup>2</sup>C Slave features:
  - Programmable I<sup>2</sup>C Address detection
  - Dual Addressing Capability to acknowledge 2 slave addresses
  - Stop bit detection
- Generation and detection of 7-bit/10-bit addressing and General Call
- Supports different communication speeds:
  - Standard Speed (up to 100 kHz),
  - Fast Speed (up to 400 kHz)
- Status flags:
  - Transmitter/Receiver mode flag
  - End-of-Byte transmission flag
  - I<sup>2</sup>C busy flag
- Error flags:
  - Arbitration lost condition for master mode
  - Acknowledgement failure after address/ data transmission
  - Detection of misplaced start or stop condition
  - Overrun/Underrun if clock stretching is disabled
- 2 Interrupt vectors:
  - 1 Interrupt for successful address/ data communication
  - 1 Interrupt for error condition
- Optional clock stretching
- 1-byte buffer with DMA capability

- Configurable PEC (packet error checking) generation or verification:
  - PEC value can be transmitted as last byte in Tx mode
  - PEC error checking for last received byte
- SMBus 2.0 Compatibility:
  - 25 ms clock low timeout delay
  - 10 ms master cumulative clock low extend time
  - 25 ms slave cumulative clock low extend time
  - Hardware PEC generation/verification with ACK control
  - Address Resolution Protocol (ARP) supported
- PMBus Compatibility

*Note:* Some of the above features may not be available in certain products. The user should refer to the product data sheet, to identify the specific features supported by the I<sup>2</sup>C interface implementation.

## 21.3 I<sup>2</sup>C functional description

In addition to receiving and transmitting data, this interface converts it from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I<sup>2</sup>C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz) or fast (up to 400 kHz) I<sup>2</sup>C bus.

### 21.3.1 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver

By default, it operates in slave mode. The interface automatically switches from slave to master, after it generates a START condition and from master to slave, if an arbitration loss or a Stop generation occurs, allowing multimaster capability.

#### Communication flow

In Master mode, the I<sup>2</sup>C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a start condition and ends with a stop condition. Both start and stop conditions are generated in master mode by software.

In Slave mode, the interface is capable of recognizing its own addresses (7 or 10-bit), and the General Call address. The General Call address detection may be enabled or disabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the start condition contain the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in Master mode.

A 9th clock pulse follows the 8 clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter. Refer to [Figure 160](#).

Figure 160. I<sup>2</sup>C bus protocol

Acknowledge may be enabled or disabled by software. The I<sup>2</sup>C interface addresses (dual addressing 7-bit/ 10-bit and/or general call address) can be selected by software.

The block diagram of the I<sup>2</sup>C interface is shown in [Figure 161](#).

Figure 161. I<sup>2</sup>C block diagram

1. SMBA is an optional signal in SMBus mode. This signal is not applicable if SMBus is disabled.

### 21.3.2 I<sup>2</sup>C slave mode

By default the I<sup>2</sup>C interface operates in Slave mode. To switch from default Slave mode to Master mode a Start condition generation is needed.

The peripheral input clock must be programmed in the I2C\_CR2 register in order to generate correct timings. The peripheral input clock frequency must be at least:

- 2 MHz in Standard mode
- 4 MHz in Fast mode

As soon as a start condition is detected, the address is received from the SDA line and sent to the shift register. Then it is compared with the address of the interface (OAR1) and with OAR2 (if ENDUAL=1) or the General Call address (if ENGC = 1).

*Note:* In 10-bit addressing mode, the comparison includes the header sequence (11110xx0), where xx denotes the two most significant bits of the address.

**Header or address not matched:** the interface ignores it and waits for another Start condition.

**Header matched** (10-bit mode only): the interface generates an acknowledge pulse if the ACK bit is set and waits for the 8-bit slave address.

**Address matched:** the interface generates in sequence:

- An acknowledge pulse if the ACK bit is set
- The ADDR bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.
- If ENDUAL=1, the software has to read the DUALF bit to check which slave address has been acknowledged.

In 10-bit mode, after receiving the address sequence the slave is always in Receiver mode. It will enter Transmitter mode on receiving a repeated Start condition followed by the header sequence with matching address bits and the least significant bit set (11110xx1).

The TRA bit indicates whether the slave is in Receiver or Transmitter mode.

#### Slave transmitter

Following the address reception and after clearing ADDR, the slave sends bytes from the DR register to the SDA line via the internal shift register.

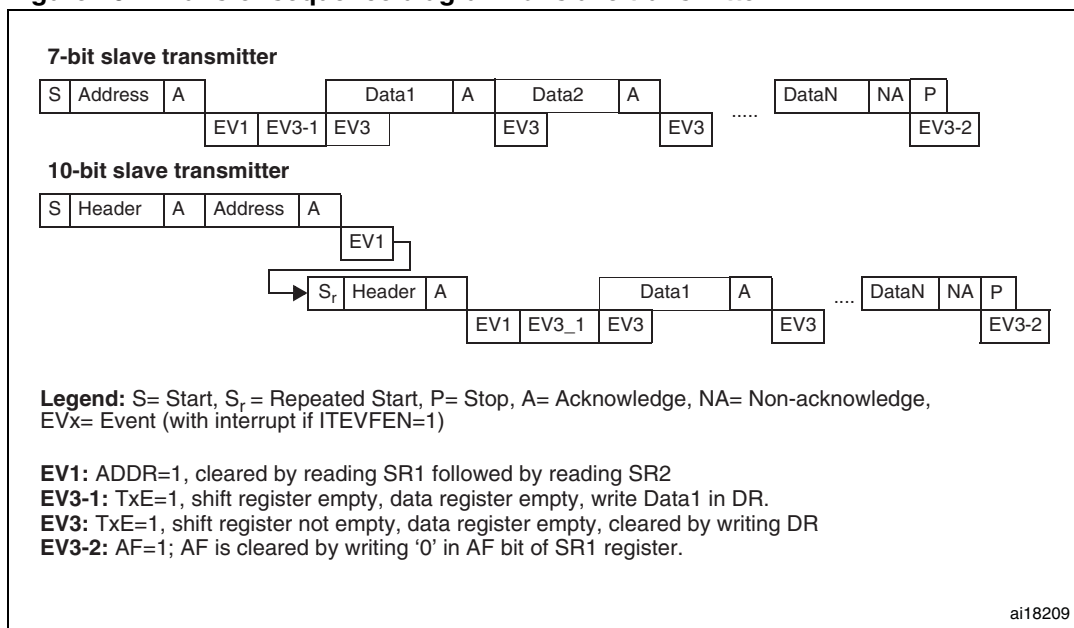

The slave stretches SCL low until ADDR is cleared and DR filled with the data to be sent (see [Figure 162](#) Transfer sequencing EV1 EV3).

When the acknowledge pulse is received:

- The TxE bit is set by hardware with an interrupt if the ITEVFEN and the ITBUFEN bits are set.

If TxE is set and some data were not written in the I2C\_DR register before the end of the next data transmission, the BTF bit is set and the interface waits until BTF is cleared by a read to I2C\_SR1 followed by a write to the I2C\_DR register, stretching SCL low.

**Figure 162. Transfer sequence diagram for slave transmitter**

1. The EV1 and EV3\_1 events stretch SCL low until the end of the corresponding software sequence.
2. The EV3 event stretches SCL low if the software sequence is not completed before the end of the next byte transmission.

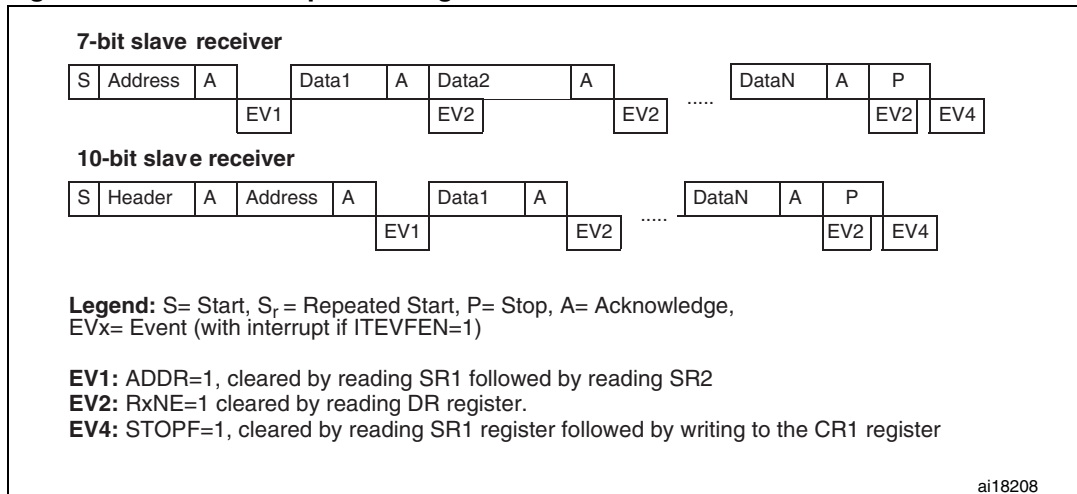

**Slave receiver**

Following the address reception and after clearing ADDR, the slave receives bytes from the SDA line into the DR register via the internal shift register. After each byte the interface generates in sequence:

- An acknowledge pulse if the ACK bit is set
- The RxNE bit is set by hardware and an interrupt is generated if the ITEVFEN and ITBUFEN bit is set.

If RxNE is set and the data in the DR register is not read before the end of the next data reception, the BTF bit is set and the interface waits until BTF is cleared by a read from the I2C\_DR register, stretching SCL low (see [Figure 163](#) Transfer sequencing).

**Figure 163. Transfer sequence diagram for slave receiver**

1. The EV1 event stretches SCL low until the end of the corresponding software sequence.
2. The EV2 event stretches SCL low if the software sequence is not completed before the end of the next byte reception.
3. After checking the SR1 register content, the user should perform the complete clearing sequence for each flag found set.  
 Thus, for ADDR and STOPF flags, the following sequence is required inside the I2C interrupt routine:  
 READ SR1  
 if (ADDR == 1) {READ SR1; READ SR2}  
 if (STOPF == 1) {READ SR1; WRITE CR1}

The purpose is to make sure that both ADDR and STOPF flags are cleared if both are found set.

### Closing slave communication

After the last data byte is transferred a Stop Condition is generated by the master. The interface detects this condition:

- The STOPF bit is set and generates an interrupt if the ITEVFEN bit is set.

The STOPF is cleared by a read of the SR1 register followed by a write to the CR1 register (see [Figure 163](#) Transfer sequencing EV4).

### 21.3.3 I<sup>2</sup>C master mode

In Master mode, the I<sup>2</sup>C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a Start condition and ends with a Stop condition. Master mode is selected as soon as the Start condition is generated on the bus with a START bit.

The following is the required sequence in master mode.

- Program the peripheral input clock in I2C\_CR2 Register in order to generate correct timings
- Configure the clock control registers
- Configure the rise time register
- Program the I2C\_CR1 register to enable the peripheral
- Set the START bit in the I2C\_CR1 register to generate a Start condition

The peripheral input clock frequency must be at least:

- 2 MHz in Standard mode
- 4 MHz in Fast mode

### Start condition

Setting the START bit causes the interface to generate a Start condition and to switch to Master mode (M/SL bit set) when the BUSY bit is cleared.

*Note:* In master mode, setting the START bit causes the interface to generate a ReStart condition at the end of the current byte transfer.

Once the Start condition is sent:

- The SB bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a write in the DR register with the Slave address (see [Figure 164](#) & [Figure 165](#) Transfer sequencing EV5).

### Slave address transmission

Then the slave address is sent to the SDA line via the internal shift register.

- In 10-bit addressing mode, sending the header sequence causes the following event:
  - The ADD10 bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a write in the DR register with the second address byte (see [Figure 164](#) & [Figure 165](#) Transfer sequencing).

- The ADDR bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a read of the SR2 register (see [Figure 164](#) & [Figure 165](#) Transfer sequencing).

- In 7-bit addressing mode, one address byte is sent.

As soon as the address byte is sent,

- The ADDR bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a read of the SR2 register (see [Figure 164](#) & [Figure 165](#) Transfer sequencing).

The master can decide to enter Transmitter or Receiver mode depending on the LSB of the slave address sent.

- In 7-bit addressing mode,
  - To enter Transmitter mode, a master sends the slave address with LSB reset.
  - To enter Receiver mode, a master sends the slave address with LSB set.
- In 10-bit addressing mode,
  - To enter Transmitter mode, a master sends the header (11110xx0) and then the slave address, (where xx denotes the two most significant bits of the address).
  - To enter Receiver mode, a master sends the header (11110xx0) and then the slave address. Then it should send a repeated Start condition followed by the header (11110xx1), (where xx denotes the two most significant bits of the address).

The TRA bit indicates whether the master is in Receiver or Transmitter mode.

### Master transmitter

Following the address transmission and after clearing ADDR, the master sends bytes from the DR register to the SDA line via the internal shift register.

The master waits until the first data byte is written into I2C\_DR (see *Figure 164* Transfer sequencing EV8\_1).

When the acknowledge pulse is received:

- The TxE bit is set by hardware and an interrupt is generated if the ITEVFEN and ITBUFEN bits are set.

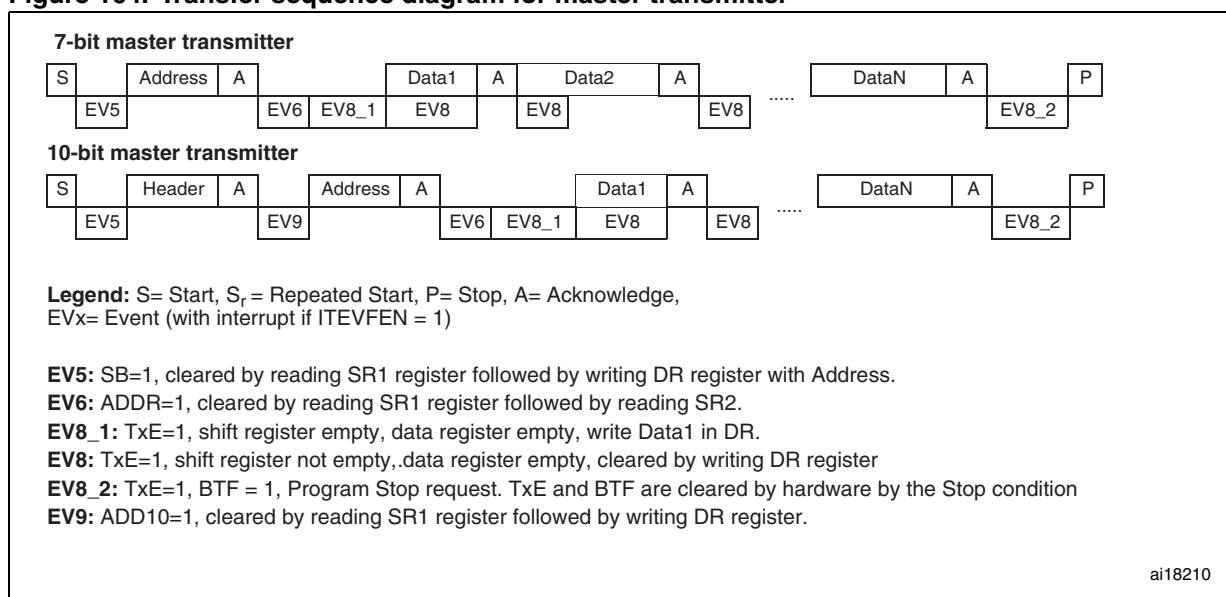

If TxE is set and a data byte was not written in the DR register before the end of the last data transmission, BTF is set and the interface waits until BTF is cleared by a write to I2C\_DR, stretching SCL low.

### Closing the communication

After the last byte is written to the DR register, the STOP bit is set by software to generate a Stop condition (see *Figure 164* Transfer sequencing EV8\_2). The interface automatically goes back to slave mode (M/SL bit cleared).

*Note:* Stop condition should be programmed during EV8\_2 event, when either TxE or BTF is set.

**Figure 164. Transfer sequence diagram for master transmitter**

1. The EV5, EV6, EV9, EV8\_1 and EV8\_2 events stretch SCL low until the end of the corresponding software sequence.
2. The EV8 event stretches SCL low if the software sequence is not complete before the end of the next byte transmission..

### Master receiver

Following the address transmission and after clearing ADDR, the I<sup>2</sup>C interface enters Master Receiver mode. In this mode the interface receives bytes from the SDA line into the DR register via the internal shift register. After each byte the interface generates in sequence:

1. An acknowledge pulse if the ACK bit is set
2. The RxNE bit is set and an interrupt is generated if the ITEVFEN and ITBUFEN bits are set (see [Figure 165](#) Transfer sequencing EV7).

If the RxNE bit is set and the data in the DR register is not read before the end of the last data reception, the BTF bit is set by hardware and the interface waits until BTF is cleared by a read in the DR register, stretching SCL low.

### Closing the communication

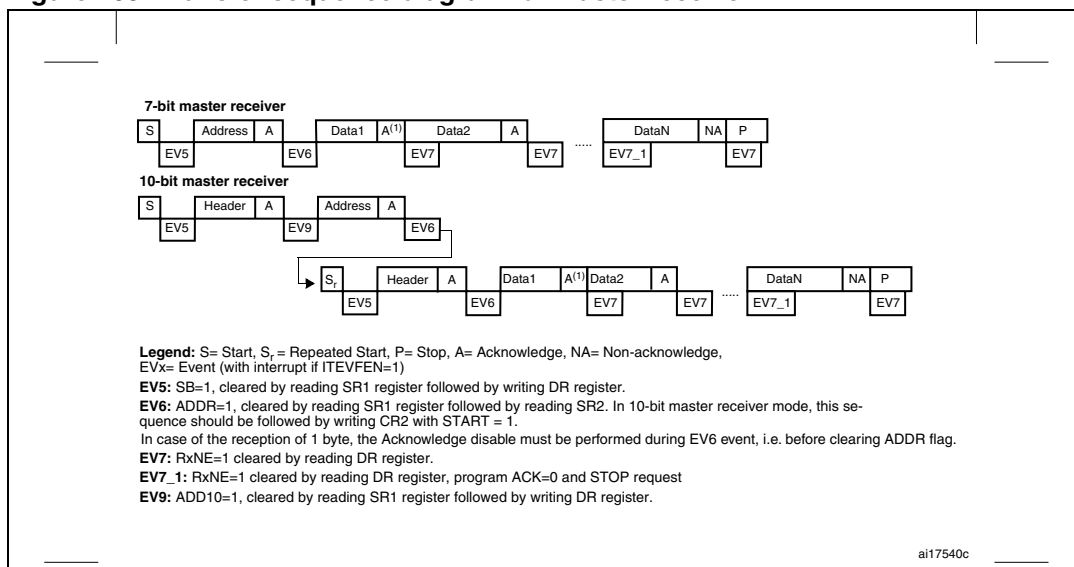

The master sends a NACK for the last byte received from the slave. After receiving this NACK, the slave releases the control of the SCL and SDA lines. Then the master can send a Stop/Restart condition.

1. To generate the nonacknowledge pulse after the last received data byte, the ACK bit must be cleared just after reading the second last data byte (after second last RxNE event).
2. In order to generate the Stop/Restart condition, software must set the STOP/START bit after reading the second last data byte (after the second last RxNE event).
3. In case a single byte has to be received, the Acknowledge disable is made during EV6 (before ADDR flag is cleared) and the STOP condition generation is made after EV6.

After the Stop condition generation, the interface goes automatically back to slave mode (M/SL bit cleared).

Figure 165. Transfer sequence diagram for master receiver

1. If a single byte is received, it is NA.
2. The EV5, EV6 and EV9 events stretch SCL low until the end of the corresponding software sequence.
3. The EV7 event stretches SCL low if the software sequence is not completed before the end of the next byte reception.
4. The EV7\_1 software sequence must be completed before the ACK pulse of the current byte transfer.

The procedures described below are recommended if the EV7-1 software sequence is not completed before the ACK pulse of the current byte transfer.

These procedures must be followed to make sure:

- The ACK bit is set low on time before the end of the last data reception
- The STOP bit is set high after the last data reception without reception of supplementary data.

**For 2-byte reception:**

- Wait until ADDR = 1 (SCL stretched low until the ADDR flag is cleared)
- Set ACK low, set POS high
- Clear ADDR flag
- Wait until BTF = 1 (Data 1 in DR, Data2 in shift register, SCL stretched low until a data 1 is read)
- Set STOP high
- Read datas 1 & 2

**For N >2 -byte reception, from N-2 data reception**

- Wait until BTF = 1 (data N-2 in DR, data N-1 in shift register, SCL stretched low until data N-2 is read)
- Set ACK low
- Read data N-2
- Wait until BTF = 1 (data N-1 in DR, data N in shift register, SCL stretched low until a data N-1 is read)
- Set STOP high
- Read datas N-1 & N

### 21.3.4 Error conditions

The following are the error conditions which may cause communication to fail.

#### Bus error (BERR)

This error occurs when the I<sup>2</sup>C interface detects an external Stop or Start condition during an address or a data transfer. In this case:

- the BERR bit is set and an interrupt is generated if the ITERREN bit is set
- in Slave mode: data are discarded and the lines are released by hardware:
  - in case of a misplaced Start, the slave considers it is a restart and waits for an address, or a Stop condition
  - in case of a misplaced Stop, the slave behaves like for a Stop condition and the lines are released by hardware
- In Master mode: the lines are not released and the state of the current transmission is not affected. It is up to the software to abort or not the current transmission

#### Acknowledge failure (AF)

This error occurs when the interface detects a nonacknowledge bit. In this case:

- the AF bit is set and an interrupt is generated if the ITERREN bit is set
- a transmitter which receives a NACK must reset the communication:
  - If Slave: lines are released by hardware
  - If Master: a Stop or repeated Start condition must be generated by software

#### Arbitration lost (ARLO)

This error occurs when the I<sup>2</sup>C interface detects an arbitration lost condition. In this case,

- the ARLO bit is set by hardware (and an interrupt is generated if the ITERREN bit is set)
- the I<sup>2</sup>C Interface goes automatically back to slave mode (the M/SL bit is cleared). When the I<sup>2</sup>C loses the arbitration, it is not able to acknowledge its slave address in the same transfer, but it can acknowledge it after a repeated Start from the winning master.
- lines are released by hardware

#### Overrun/underrun error (OVR)

An overrun error can occur in slave mode when clock stretching is disabled and the I<sup>2</sup>C interface is receiving data. The interface has received a byte (RxNE=1) and the data in DR has not been read, before the next byte is received by the interface. In this case,

- The last received byte is lost.
- In case of Overrun error, software should clear the RxNE bit and the transmitter should re-transmit the last received byte.

Underrun error can occur in slave mode when clock stretching is disabled and the I<sup>2</sup>C interface is transmitting data. The interface has not updated the DR with the next byte (TxE=1), before the clock comes for the next byte. In this case,

- The same byte in the DR register will be sent again
- The user should make sure that data received on the receiver side during an underrun error are discarded and that the next bytes are written within the clock low time specified in the I<sup>2</sup>C bus standard.

For the first byte to be transmitted, the DR must be written after ADDR is cleared and before the first SCL rising edge. If not possible, the receiver must discard the first data.

### 21.3.5 SDA/SCL line control

- If clock stretching is enabled:
  - Transmitter mode: If TxE=1 and BTF=1: the interface holds the clock line low before transmission to wait for the microcontroller to write the byte in the Data Register (both buffer and shift register are empty).
  - Receiver mode: If RxNE=1 and BTF=1: the interface holds the clock line low after reception to wait for the microcontroller to read the byte in the Data Register (both buffer and shift register are full).
- If clock stretching is disabled in Slave mode:
  - Overrun Error in case of RxNE=1 and no read of DR has been done before the next byte is received. The last received byte is lost.
  - Underrun Error in case TxE=1 and no write into DR has been done before the next byte must be transmitted. The same byte will be sent again.
  - Write Collision not managed.

### 21.3.6 SMBus

#### Introduction

The System Management Bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I<sup>2</sup>C principles of operation. SMBus provides a control bus for system and power management related tasks. A system may use SMBus to pass messages to and from devices instead of toggling individual control lines.

The System Management Bus Specification refers to three types of devices. A *slave* is a device that is receiving or responding to a command. A *master* is a device that issues commands, generates the clocks, and terminates the transfer. A *host* is a specialized master that provides the main interface to the system's CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

#### Similarities between SMBus and I<sup>2</sup>C

- 2 wire bus protocol (1 Clk, 1 Data) + SMBus Alert line optional
- Master-slave communication, Master provides clock
- Multi master capability
- SMBus data format similar to I<sup>2</sup>C 7-bit addressing format ([Figure 160](#)).

#### Differences between SMBus and I<sup>2</sup>C

The following table describes the differences between SMBus and I<sup>2</sup>C.

**Table 78. SMBus vs. I<sup>2</sup>C**

SMBus	I <sup>2</sup> C
Max. speed 100 kHz	Max. speed 400 kHz
Min. clock speed 10 kHz	No minimum clock speed

**Table 78. SMBus vs. I<sup>2</sup>C (continued)**

SMBus	I <sup>2</sup> C
35 ms clock low timeout	No timeout
Logic levels are fixed	Logic levels are V <sub>DD</sub> dependent
Different address types (reserved, dynamic etc.)	7-bit, 10-bit and general call slave address types
Different bus protocols (quick command, process call etc.)	No bus protocols

### SMBus application usage

With System Management Bus, a device can provide manufacturer information, tell the system what its model/part number is, save its state for a suspend event, report different types of errors, accept control parameters, and return its status. SMBus provides a control bus for system and power management related tasks.

### Device identification

Any device that exists on the System Management Bus as a slave has a unique address called the Slave Address. For the list of reserved slave addresses, refer to the SMBus specification ver. 2.0 (<http://smbus.org/specs/>).

### Bus protocols

The SMBus specification supports up to 9 bus protocols. For more details of these protocols and SMBus address types, refer to SMBus specification ver. 2.0 (<http://smbus.org/specs/>). These protocols should be implemented by the user software.

### Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. The Address Resolution Protocol (ARP) has the following attributes:

- Address assignment uses the standard SMBus physical layer arbitration mechanism
- Assigned addresses remain constant while device power is applied; address retention through device power loss is also allowed
- No additional SMBus packet overhead is incurred after address assignment. (i.e. subsequent accesses to assigned slave addresses have the same overhead as accesses to fixed address devices.)
- Any SMBus master can enumerate the bus

### Unique device identifier (UDID)

In order to provide a mechanism to isolate each device for the purpose of address assignment, each device must implement a unique device identifier (UDID).

For the details on 128 bit UDID and more information on ARP, refer to SMBus specification ver. 2.0 (<http://smbus.org/specs/>).

### SMBus alert mode

SMBus Alert is an optional signal with an interrupt line for devices that want to trade their ability to master for a pin. SMBA is a wired-AND signal just as the SCL and SDA signals are.

SMBA is used in conjunction with the SMBus General Call Address. Messages invoked with the SMBus are 2 bytes long.

A slave-only device can signal the host through SMBA that it wants to talk by setting ALERT bit in I2C\_CR1 register. The host processes the interrupt and simultaneously accesses all SMBA devices through the *Alert Response Address* (known as ARA having a value 0001 100X). Only the device(s) which pulled SMBA low will acknowledge the Alert Response Address. This status is identified using SMBALERT Status flag in I2C\_SR1 register. The host performs a modified Receive Byte operation. The 7 bit device address provided by the slave transmit device is placed in the 7 most significant bits of the byte. The eighth bit can be a zero or one.

If more than one device pulls SMBA low, the highest priority (lowest address) device will win communication rights via standard arbitration during the slave address transfer. After acknowledging the slave address the device must disengage its SMBA pull-down. If the host still sees SMBA low when the message transfer is complete, it knows to read the ARA again.

A host which does not implement the SMBA signal may periodically access the ARA.

For more details on SMBus Alert mode, refer to SMBus specification ver. 2.0 (<http://smbus.org/specs/>).

### Timeout error

There are differences in the timing specifications between I<sup>2</sup>C and SMBus. SMBus defines a clock low timeout, TIMEOUT of 35 ms. Also SMBus specifies TLOW: SEXT as the cumulative clock low extend time for a slave device. SMBus specifies TLOW: MEXT as the cumulative clock low extend time for a master device. For more details on these timeouts, refer to SMBus specification ver. 2.0 (<http://smbus.org/specs/>).

The status flag Timeout or Tlow Error in I2C\_SR1 shows the status of this feature.

### How to use the interface in SMBus mode

To switch from I<sup>2</sup>C mode to SMBus mode, the following sequence should be performed.

- Set the SMBus bit in the I2C\_CR1 register
- Configure the SMBTYPE and ENARP bits in the I2C\_CR1 register as required for the application

If you want to configure the device as a master, follow the Start condition generation procedure in [Section 21.3.3: I2C master mode](#). Otherwise, follow the sequence in [Section 21.3.2: I2C slave mode](#).

The application has to control the various SMBus protocols by software.

- SMB Device Default Address acknowledged if ENARP=1 and SMBTYPE=0
- SMB Host Header acknowledged if ENARP=1 and SMBTYPE=1
- SMB Alert Response Address acknowledged if SMBALERT=1

## 21.3.7 DMA requests

DMA requests (when enabled) are generated only for data transfer. DMA requests are generated by Data Register becoming empty in transmission and Data Register becoming full in reception. The DMA request must be served before the end of the current byte transfer. When the number of data transfers which has been programmed for the

corresponding DMA channel is reached, the DMA controller sends an End of Transfer EOT signal to the I<sup>2</sup>C interface and generates a Transfer Complete interrupt if enabled:

- Master transmitter: In the interrupt routine after the EOT interrupt, disable DMA requests then wait for a BTF event before programming the Stop condition.
- Master receiver:
  - when the number of bytes to be received is equal to or greater than two, the DMA controller sends a hardware signal, EOT\_1, corresponding to the last but one data byte (number\_of\_bytes – 1). If, in the I2C\_CR2 register, the LAST bit is set, I<sup>2</sup>C automatically sends a NACK after the next byte following EOT\_1. The user can generate a Stop condition in the DMA Transfer Complete interrupt routine if enabled.
  - when a single byte must be received : the NACK must be programmed during EV6 event, i.e. program ACK=0 when ADDR=1, before clearing ADDR flag. Then the user can program the STOP condition either after clearing ADDR flag, or in the DMA Transfer Complete interrupt routine.

### Transmission using DMA

DMA mode can be enabled for transmission by setting the DMAEN bit in the I2C\_CR2 register. Data will be loaded from a Memory area configured using the DMA peripheral (refer to the DMA specification) to the I2C\_DR register whenever the TxE bit is set. To map a DMA channel for I<sup>2</sup>C transmission, perform the following sequence. Here x is the channel number.

1. Set the I2C\_DR register address in the DMA\_CPARx register. The data will be moved to this address from the memory after each TxE event.
2. Set the memory address in the DMA\_CMARx register. The data will be loaded into I2C\_DR from this memory after each TxE event.
3. Configure the total number of bytes to be transferred in the DMA\_CNDTRx register. After each TxE event, this value will be decremented.
4. Configure the channel priority using the PL[0:1] bits in the DMA\_CCRx register
5. Set the DIR bit and, in the DMA\_CCRx register, configure interrupts after half transfer or full transfer depending on application requirements.
6. Activate the channel by setting the EN bit in the DMA\_CCRx register.

When the number of data transfers which has been programmed in the DMA Controller registers is reached, the DMA controller sends an End of Transfer EOT/ EOT\_1 signal to the I<sup>2</sup>C interface and the DMA generates an interrupt, if enabled, on the DMA channel interrupt vector.

*Note:* Do not enable the ITBUFEN bit in the I2C\_CR2 register if DMA is used for transmission.

### Reception using DMA

DMA mode can be enabled for reception by setting the DMAEN bit in the I2C\_CR2 register. Data will be loaded from the I2C\_DR register to a Memory area configured using the DMA peripheral (refer to the DMA specification) whenever a data byte is received. To map a DMA channel for I<sup>2</sup>C reception, perform the following sequence. Here x is the channel number.

1. Set the I2C\_DR register address in DMA\_CPARx register. The data will be moved from this address to the memory after each RxNE event.
2. Set the memory address in the DMA\_CMARx register. The data will be loaded from the I2C\_DR register to this memory area after each RxNE event.
3. Configure the total number of bytes to be transferred in the DMA\_CNDTRx register. After each RxNE event, this value will be decremented.
4. Configure the channel priority using the PL[0:1] bits in the DMA\_CCRx register
5. Reset the DIR bit and configure interrupts in the DMA\_CCRx register after half transfer or full transfer depending on application requirements.
6. Activate the channel by setting the EN bit in the DMA\_CCRx register.

When the number of data transfers which has been programmed in the DMA Controller registers is reached, the DMA controller sends an End of Transfer EOT/ EOT\_1 signal to the I<sup>2</sup>C interface and DMA generates an interrupt, if enabled, on the DMA channel interrupt vector.

*Note:* Do not enable the ITBUFEN bit in the I2C\_CR2 register if DMA is used for reception.

### 21.3.8 Packet error checking

A PEC calculator has been implemented to improve the reliability of communication. The PEC is calculated by using the  $C(x) = x^8 + x^2 + x + 1$  CRC-8 polynomial serially on each bit.

- PEC calculation is enabled by setting the ENPEC bit in the I2C\_CR1 register. PEC is a CRC-8 calculated on all message bytes including addresses and R/W bits.
  - In transmission: set the PEC transfer bit in the I2C\_CR1 register after the TxE event corresponding to the last byte. The PEC will be transferred after the last transmitted byte.
  - In reception: set the PEC bit in the I2C\_CR1 register after the RxNE event corresponding to the last byte so that the receiver sends a NACK if the next received byte is not equal to the internally calculated PEC. In case of Master-Receiver, a NACK must follow the PEC whatever the check result. The PEC must be set before the ACK of the CRC reception in slave mode. It must be set when the ACK is set low in master mode.
- A PECERR error flag/interrupt is also available in the I2C\_SR1 register.
- If DMA and PEC calculation are both enabled:-
  - In transmission: when the I<sup>2</sup>C interface receives an EOT signal from the DMA controller, it automatically sends a PEC after the last byte.
  - In reception: when the I<sup>2</sup>C interface receives an EOT\_1 signal from the DMA controller, it will automatically consider the next byte as a PEC and will check it. A DMA request is generated after PEC reception.
- To allow intermediate PEC transfers, a control bit is available in the I2C\_CR2 register (LAST bit) to determine if it is really the last DMA transfer or not. If it is the last DMA request for a master receiver, a NACK is automatically sent after the last received byte.
- PEC calculation is corrupted by an arbitration loss.

## 21.4 I<sup>2</sup>C interrupts

The table below gives the list of I<sup>2</sup>C interrupt requests.

**Table 79. I<sup>2</sup>C Interrupt requests**

Interrupt event	Event flag	Enable control bit
Start bit sent (Master)	SB	ITEVFEN
Address sent (Master) or Address matched (Slave)	ADDR	
10-bit header sent (Master)	ADD10	
Stop received (Slave)	STOPF	
Data byte transfer finished	BTF	
Receive buffer not empty	RxNE	ITEVFEN and ITBUFEN
Transmit buffer empty	TxE	
Bus error	BERR	ITERREN
Arbitration loss (Master)	ARLO	
Acknowledge failure	AF	
Overrun/Underrun	OVR	
PEC error	PECERR	
Timeout/Tlow error	TIMEOUT	
SMBus Alert	SMBALERT	

- Note:
- 1 SB, ADDR, ADD10, STOPF, BTF, RxNE and TxE are logically ORed on the same interrupt channel.
  - 2 BERR, ARLO, AF, OVR, PECERR, TIMEOUT and SMBALERT are logically ORed on the same interrupt channel.

**Figure 166. I<sup>2</sup>C interrupt mapping diagram**

## 21.5 I<sup>2</sup>C debug mode

When the microcontroller enters the debug mode (Cortex-M3 core halted), the SMBUS timeout either continues to work normally or stops, depending on the DBG\_I2Cx\_SMBUS\_TIMEOUT configuration bits in the DBG module. For more details, refer to [Section 24.16.2: Debug support for timers, watchdog and I2C on page 580](#).

## 21.6 I<sup>2</sup>C registers

Refer to [Table 21-1](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 21.6.1 Control register 1 (I2C\_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWRST	Res.	ALERT	PEC	POS	ACK	STOP	START	NO STRETCH	ENGC	ENPEC	ENARP	SMB TYPE	Res.	SMBUS	PE
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 15 **SWRST**: Software reset

When set, the I2C is under reset state. Before resetting this bit, make sure the I2C lines are released and the bus is free.

0: I<sup>2</sup>C Peripheral not under reset  
1: I<sup>2</sup>C Peripheral under reset state

*Note: This bit can be used in case the BUSY bit is set to '1 when no stop condition has been detected on the bus.*

Bit 14 Reserved, forced by hardware to 0.

Bit 13 **ALERT**: SMBus alert

This bit is set and cleared by software, and cleared by hardware when PE=0.

0: Releases SMBA pin high. Alert Response Address Header followed by NACK.  
1: Drives SMBA pin low. Alert Response Address Header followed by ACK.

Bit 12 **PEC**: Packet error checking

This bit is set and cleared by software, and cleared by hardware when PEC is transferred or by a START or Stop condition or when PE=0.

0: No PEC transfer  
1: PEC transfer (in Tx or Rx mode)

*Note: PEC calculation is corrupted by an arbitration loss.*

Bit 11 **POS**: Acknowledge/PEC Position (for data reception)

This bit is set and cleared by software and cleared by hardware when PE=0.

0: ACK bit controls the (N)ACK of the current byte being received in the shift register. The PEC bit indicates that current byte in shift register is a PEC.  
1: ACK bit controls the (N)ACK of the next byte which will be received in the shift register. The PEC bit indicates that the next byte in the shift register is a PEC

*Note: The POS bit must be used only in 2-byte reception configuration in master mode. It must be configured before data reception starts, as described in the 2-byte reception procedure recommended in [Section : Master receiver on page 464](#).*

Bit 10 **ACK**: Acknowledge enable

This bit is set and cleared by software and cleared by hardware when PE=0.

0: No acknowledge returned

1: Acknowledge returned after a byte is received (matched address or data)

Bit 9 **STOP**: Stop generation

The bit is set and cleared by software, cleared by hardware when a Stop condition is detected, set by hardware when a timeout error is detected.

In Master Mode:

0: No Stop generation.

1: Stop generation after the current byte transfer or after the current Start condition is sent.

In Slave mode:

0: No Stop generation.

1: Release the SCL and SDA lines after the current byte transfer.

*Note: When the STOP, START or PEC bit is set, the software must not perform any write access to I2C\_CR1 before this bit is cleared by hardware. Otherwise there is a risk of setting a second STOP, START or PEC request.*

Bit 8 **START**: Start generation

This bit is set and cleared by software and cleared by hardware when start is sent or PE=0.

In Master Mode:

0: No Start generation

1: Repeated start generation

In Slave mode:

0: No Start generation

1: Start generation when the bus is free

Bit 7 **NOSTRETCH**: Clock stretching disable (Slave mode)

This bit is used to disable clock stretching in slave mode when ADDR or BTF flag is set, until it is reset by software.

0: Clock stretching enabled

1: Clock stretching disabled

Bit 6 **ENGCG**: General call enable

0: General call disabled. Address 00h is NACKed.

1: General call enabled. Address 00h is ACKed.

Bit 5 **ENPEC**: PEC enable

0: PEC calculation disabled

1: PEC calculation enabled

Bit 4 **ENARP**: ARP enable

0: ARP disable

1: ARP enable

SMBus Device default address recognized if SMBTYPE=0

SMBus Host address recognized if SMBTYPE=1

Bit 3 **SMBTYPE**: SMBus type

0: SMBus Device

1: SMBus Host

## Bit 2 Reserved, forced by hardware to 0.

Bit 1 **SMBUS**: SMBus mode

0: I<sup>2</sup>C mode

1: SMBus mode

Bit 0 **PE**: Peripheral enable

0: Peripheral disable

1: Peripheral enable: the corresponding IOs are selected as alternate functions depending on SMBus bit.

*Note: If this bit is reset while a communication is on going, the peripheral is disabled at the end of the current communication, when back to IDLE state.*

*All bit resets due to PE=0 occur at the end of the communication.*

*In master mode, this bit must not be reset before the end of the communication.*

### 21.6.2 Control register 2 (I2C\_CR2)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			LAST	DMA EN	ITBUF EN	ITEVT EN	ITERR EN	Reserved			FREQ[5:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 15:13 Reserved, forced by hardware to 0.

Bit 12 **LAST**: DMA last transfer

0: Next DMA EOT is not the last transfer

1: Next DMA EOT is the last transfer

*Note: This bit is used in master receiver mode to permit the generation of a NACK on the last received data.*

Bit 11 **DMAEN**: DMA requests enable

0: DMA requests disabled

1: DMA request enabled when TxE=1 or RxNE =1

Bit 10 **ITBUFEN**: Buffer interrupt enable

0: TxE = 1 or RxNE = 1 does not generate any interrupt.

1:TxE = 1 or RxNE = 1 generates Event Interrupt (whatever the state of DMAEN)

Bit 9 **ITEVTEN**: Event interrupt enable

0: Event interrupt disabled

1: Event interrupt enabled

This interrupt is generated when:

–SB = 1 (Master)

–ADDR = 1 (Master/Slave)

–ADD10= 1 (Master)

–STOPF = 1 (Slave)

–BTF = 1 with no TxE or RxNE event

–TxE event to 1 if ITBUFEN = 1

–RxNE event to 1if ITBUFEN = 1

Bit 8 **ITERREN**: Error interrupt enable

- 0: Error interrupt disabled
- 1: Error interrupt enabled

This interrupt is generated when:

- BERR = 1
- ARLO = 1
- AF = 1
- OVR = 1
- PECERR = 1
- TIMEOUT = 1
- SMBALERT = 1

Bits 7:6 Reserved, forced by hardware to 0.

Bits 5:0 **FREQ[5:0]**: Peripheral clock frequency

The peripheral clock frequency must be configured using the input APB clock frequency (I2C peripheral connected to APB1). The minimum allowed frequency is 2 MHz, the maximum frequency is limited by the maximum APB1 frequency (32 MHz) and an intrinsic limitation of 46 MHz.

- 0b000000: Not allowed
- 0b000001: Not allowed
- 0b000010: 2 MHz
- ...
- 0b100000: 32 MHz
- Higher than 0b100000: Not allowed

### 21.6.3 Own address register 1 (I2C\_OAR1)

Address offset: 0x08  
Reset value: 0x0000

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	ADD MODE			Reserved			ADD[9:8]		ADD[7:1]							ADD0	
	rw						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 15 **ADDMODE** Addressing mode (slave mode)  
 0: 7-bit slave address (10-bit address not acknowledged)  
 1: 10-bit slave address (7-bit address not acknowledged)

Bit 14 Should always be kept at 1 by software.

Bits 13:10 Reserved, forced by hardware to 0.

Bits 9:8 **ADD[9:8]**: Interface address  
 7-bit addressing mode: don't care  
 10-bit addressing mode: bits9:8 of address

Bits 7:1 **ADD[7:1]**: Interface address  
 bits 7:1 of address

Bit 0 **ADD0**: Interface address  
 7-bit addressing mode: don't care  
 10-bit addressing mode: bit 0 of address

### 21.6.4 Own address register 2 (I2C\_OAR2)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								ADD2[7:1]							ENDUAL	
								rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:8 Reserved, forced by hardware to 0.

Bits 7:1 **ADD2[7:1]**: Interface address  
bits 7:1 of address in dual addressing mode

Bit 0 **ENDUAL**: Dual addressing mode enable  
0: Only OAR1 is recognized in 7-bit addressing mode  
1: Both OAR1 and OAR2 are recognized in 7-bit addressing mode

### 21.6.5 Data register (I2C\_DR)

Address offset: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								DR[7:0]								
								rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:8 Reserved, forced by hardware to 0.

Bits 7:0 **DR[7:0]** 8-bit data register

Byte received or to be transmitted to the bus.

–Transmitter mode: Byte transmission starts automatically when a byte is written in the DR register. A continuous transmit stream can be maintained if the next data to be transmitted is put in DR once the transmission is started (TxE=1)

–Receiver mode: Received byte is copied into DR (RxNE=1). A continuous transmit stream can be maintained if DR is read before the next data byte is received (RxNE=1).

*Note: In slave mode, the address is not copied into DR.*

*Note: Write collision is not managed (DR can be written if TxE=0).*

*Note: If an ARLO event occurs on ACK pulse, the received byte is not copied into DR and so cannot be read.*

### 21.6.6 Status register 1 (I2C\_SR1)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMB ALERT	TIME OUT	Res.	PEC ERR	OVR	AF	ARLO	BERR	TxE	RxNE	Res.	STOPF	ADD10	BTF	ADDR	SB
rc_w0	rc_w0		rc_w0	rc_w0	rc_w0	rc_w0	rc_w0	r	r		r	r	r	r	r

Bit 15 **SMBALERT**: SMBus alert

In SMBus host mode:

0: no SMBALERT

1: SMBALERT event occurred on pin

In SMBus slave mode:

0: no SMBALERT response address header

1: SMBALERT response address header to SMBALERT LOW received

– Cleared by software writing 0, or by hardware when PE=0.

Bit 14 **TIMEOUT**: Timeout or Tlow error

0: No timeout error

1: SCL remained LOW for 25 ms (Timeout)

or

Master cumulative clock low extend time more than 10 ms (Tlow:mext)

or

Slave cumulative clock low extend time more than 25 ms (Tlow:sext)

– When set in slave mode: slave resets the communication and lines are released by hardware

– When set in master mode: Stop condition sent by hardware

– Cleared by software writing 0, or by hardware when PE=0.

*Note: This functionality is available only in SMBus mode.*

Bit 13 Reserved, forced by hardware to 0.

Bit 12 **PECERR**: PEC Error in reception

0: no PEC error: receiver returns ACK after PEC reception (if ACK=1)

1: PEC error: receiver returns NACK after PEC reception (whatever ACK)

–Cleared by software writing 0, or by hardware when PE=0.

*Note: When the received CRC is wrong, PECERR is not set in slave mode if the PEC control bit is not set before the end of the CRC reception. Nevertheless, reading the PEC value determines whether the received CRC is right or wrong.*

Bit 11 **OVR**: Overrun/Underrun

0: No overrun/underrun

1: Overrun or underrun

–Set by hardware in slave mode when NOSTRETCH=1 and:

–In reception when a new byte is received (including ACK pulse) and the DR register has not been read yet. New received byte is lost.

–In transmission when a new byte should be sent and the DR register has not been written yet. The same byte is sent twice.

–Cleared by software writing 0, or by hardware when PE=0.

*Note: If the DR write occurs very close to SCL rising edge, the sent data is unspecified and a hold timing error occurs*

- Bit 10 **AF**: Acknowledge failure
- 0: No acknowledge failure
  - 1: Acknowledge failure
- Set by hardware when no acknowledge is returned.  
–Cleared by software writing 0, or by hardware when PE=0.
- Bit 9 **ARLO**: Arbitration lost (master mode)
- 0: No Arbitration Lost detected
  - 1: Arbitration Lost detected
- Set by hardware when the interface loses the arbitration of the bus to another master  
–Cleared by software writing 0, or by hardware when PE=0.  
After an ARLO event the interface switches back automatically to Slave mode (M/SL=0).
- Note: In SMBUS, the arbitration on the data in slave mode occurs only during the data phase, or the acknowledge transmission (not on the address acknowledge).*
- Bit 8 **BERR**: Bus error
- 0: No misplaced Start or Stop condition
  - 1: Misplaced Start or Stop condition
- Set by hardware when the interface detects an SDA rising or falling edge while SCL is high, occurring in a non-valid position during a byte transfer.  
–Cleared by software writing 0, or by hardware when PE=0.
- Bit 7 **TxE**: Data register empty (transmitters)
- 0: Data register not empty
  - 1: Data register empty
- Set when DR is empty in transmission. TxE is not set during address phase.  
–Cleared by software writing to the DR register or by hardware after a start or a stop condition or when PE=0.  
TxE is not set if either a NACK is received, or if next byte to be transmitted is PEC (PEC=1)
- Note: TxE is not cleared by writing the first data being transmitted, or by writing data when BTF is set, as in both cases the data register is still empty.*
- Bit 6 **RxNE**: Data register not empty (receivers)
- 0: Data register empty
  - 1: Data register not empty
- Set when data register is not empty in receiver mode. RxNE is not set during address phase.  
–Cleared by software reading or writing the DR register or by hardware when PE=0.  
RxNE is not set in case of ARLO event.
- Note: RxNE is not cleared by reading data when BTF is set, as the data register is still full.*
- Bit 5 Reserved, forced by hardware to 0.
- Bit 4 **STOPF**: Stop detection (slave mode)
- 0: No Stop condition detected
  - 1: Stop condition detected
- Set by hardware when a Stop condition is detected on the bus by the slave after an acknowledge (if ACK=1).  
–Cleared by software reading the SR1 register followed by a write in the CR1 register, or by hardware when PE=0
- Note: The STOPF bit is not set after a NACK reception.  
It is recommended to perform the complete clearing sequence (READ SR1 then WRITE CR1) after the STOPF is set. Refer to Figure 163: Transfer sequence diagram for slave receiver on page 460.*

**Bit 3 ADD10:** 10-bit header sent (Master mode)

0: No ADD10 event occurred.

1: Master has sent first address byte (header).

–Set by hardware when the master has sent the first byte in 10-bit address mode.

–Cleared by software reading the SR1 register followed by a write in the DR register of the second address byte, or by hardware when PE=0.

*Note: ADD10 bit is not set after a NACK reception***Bit 2 BTF:** Byte transfer finished

0: Data byte transfer not done

1: Data byte transfer succeeded

–Set by hardware when NOSTRETCH=0 and:

–In reception when a new byte is received (including ACK pulse) and DR has not been read yet (RxNE=1).

–In transmission when a new byte should be sent and DR has not been written yet (TxE=1).

–Cleared by software by either a read or write in the DR register or by hardware after a start or a stop condition in transmission or when PE=0.

*Note: The BTF bit is not set after a NACK reception**The BTF bit is not set if next byte to be transmitted is the PEC (TRA=1 in I2C\_SR2 register and PEC=1 in I2C\_CR1 register)***Bit 1 ADDR:** Address sent (master mode)/matched (slave mode)

This bit is cleared by software reading SR1 register followed reading SR2, or by hardware when PE=0.

**Address matched (Slave)**

0: Address mismatched or not received.

1: Received address matched.

–Set by hardware as soon as the received slave address matched with the OAR registers content or a general call or a SMBus Device Default Address or SMBus Host or SMBus Alert is recognized. (when enabled depending on configuration).

*Note: In slave mode, it is recommended to perform the complete clearing sequence (READ SR1 then READ SR2) after ADDR is set. Refer to [Figure 163: Transfer sequence diagram for slave receiver on page 460](#).***Address sent (Master)**

0: No end of address transmission

1: End of address transmission

–For 10-bit addressing, the bit is set after the ACK of the 2nd byte.

–For 7-bit addressing, the bit is set after the ACK of the byte.

*Note: ADDR is not set after a NACK reception***Bit 0 SB:** Start bit (Master mode)

0: No Start condition

1: Start condition generated.

–Set when a Start condition generated.

–Cleared by software by reading the SR1 register followed by writing the DR register, or by hardware when PE=0

### 21.6.7 Status register 2 (I2C\_SR2)

Address offset: 0x18

Reset value: 0x0000

*Note: Reading I2C\_SR2 after reading I2C\_SR1 clears the ADDR flag, even if the ADDR flag was set after reading I2C\_SR1. Consequently, I2C\_SR2 must be read only when ADDR is found set in I2C\_SR1 or when the STOPF bit is cleared.*

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PEC[7:0]								DUALF	SMB HOST	SMBDE FAULT	GEN CALL	Res.	TRA	BUSY	MSL
r	r	r	r	r	r	r	r	r	r	r	r		r	r	r

Bits 15:8 **PEC[7:0]** Packet error checking register

This register contains the internal PEC when ENPEC=1.

Bit 7 **DUALF**: Dual flag (Slave mode)

0: Received address matched with OAR1

1: Received address matched with OAR2

–Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 6 **SMBHOST**: SMBus host header (Slave mode)

0: No SMBus Host address

1: SMBus Host address received when SMBTYPE=1 and ENARP=1.

–Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 5 **SMBDEFAULT**: SMBus device default address (Slave mode)

0: No SMBus Device Default address

1: SMBus Device Default address received when ENARP=1

–Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 4 **GENCALL**: General call address (Slave mode)

0: No General Call

1: General Call Address received when ENGC=1

–Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 3 Reserved, forced by hardware to 0.

Bit 2 **TRA**: Transmitter/receiver

0: Data bytes received

1: Data bytes transmitted

This bit is set depending on the R/W bit of the address byte, at the end of total address phase.

It is also cleared by hardware after detection of Stop condition (STOPF=1), repeated Start condition, loss of bus arbitration (ARLO=1), or when PE=0.

Bit 1 **BUSY**: Bus busy

- 0: No communication on the bus
- 1: Communication ongoing on the bus
- Set by hardware on detection of SDA or SCL low
- cleared by hardware on detection of a Stop condition.

It indicates a communication in progress on the bus. This information is still updated when the interface is disabled (PE=0).

Bit 0 **MSL**: Master/slave

- 0: Slave Mode
- 1: Master Mode
- Set by hardware as soon as the interface is in Master mode (SB=1).
- Cleared by hardware after detecting a Stop condition on the bus or a loss of arbitration (ARLO=1), or by hardware when PE=0.

### 21.6.8 Clock control register (I2C\_CCR)

Address offset: 0x1C

Reset value: 0x0000

- Note:*
- 1 To use the I2C at 400 KHz (in fast mode), the PCLK1 frequency (I2C peripheral input clock) must be a multiple of 10 MHz.
  - 2 The CCR register must be configured only when the I2C is disabled (PE = 0).

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
F/S	DUTY	Reserved			CCR[11:0]											
rw	rw				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 15 **F/S**: I2C master mode selection

- 0: Standard Mode I2C
- 1: Fast Mode I2C

Bit 14 **DUTY**: Fast mode duty cycle

- 0: Fast Mode  $t_{low}/t_{high} = 2$
- 1: Fast Mode  $t_{low}/t_{high} = 16/9$  (see CCR)

Bits 13:12 Reserved, forced by hardware to 0.

Bits 11:0 **CCR[11:0]**: Clock control register in Fast/Standard mode (Master mode)

Controls the SCL clock in master mode.

Standard mode or SMBus:

$$T_{high} = CCR * T_{PCLK1}$$

$$T_{low} = CCR * T_{PCLK1}$$

Fast mode:

If DUTY = 0:

$$T_{high} = CCR * T_{PCLK1}$$

$$T_{low} = 2 * CCR * T_{PCLK1}$$

If DUTY = 1: (to reach 400 kHz)

$$T_{high} = 9 * CCR * T_{PCLK1}$$

$$T_{low} = 16 * CCR * T_{PCLK1}$$

For instance: in standard mode, to generate a 100 kHz SCL frequency:

If FREQR = 08, T<sub>PCLK1</sub> = 125 ns so CCR must be programmed with 0x28

(0x28 <=> 40d x 125 ns = 5000 ns.)

- Note:*
1. The minimum allowed value is 0x04, except in FAST DUTY mode where the minimum allowed value is 0x01
  2. t<sub>high</sub> includes the SCLH rising edge
  3. t<sub>low</sub> includes the SCLH falling edge
  4. These timings are without filters.
  5. The CCR register must be configured only when the I<sup>2</sup>C is disabled (PE = 0).

### 21.6.9 TRISE register (I2C\_TRISE)

Address offset: 0x20

Reset value: 0x0002

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										TRISE[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 15:6 Reserved, forced by hardware to 0.

Bits 5:0 **TRISE[5:0]**: Maximum rise time in Fast/Standard mode (Master mode)

These bits must be programmed with the maximum SCL rise time given in the I<sup>2</sup>C bus specification, incremented by 1.

For instance: in standard mode, the maximum allowed SCL rise time is 1000 ns.

If, in the I2C\_CR2 register, the value of FREQ[5:0] bits is equal to 0x08 and T<sub>PCLK1</sub> = 125 ns therefore the TRISE[5:0] bits must be programmed with 09h.

$$(1000 \text{ ns} / 125 \text{ ns} = 8 + 1)$$

The filter value can also be added to TRISE[5:0].

If the result is not an integer, TRISE[5:0] must be programmed with the integer part, in order to respect the t<sub>HIGH</sub> parameter.

*Note:* TRISE[5:0] must be configured only when the I2C is disabled (PE = 0).

### 21.6.10 I<sup>2</sup>C register map

The table below provides the I<sup>2</sup>C register map and reset values.

**Table 80. I<sup>2</sup>C register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0x20	I2C_TRISE	Reserved																TRISE[5:0]																	
	Reset value																	0	0	0	0	0	0	0	1	0									

Refer to [Table 1 on page 32](#) for the register boundary addresses table.

## 22 Serial peripheral interface (SPI)

### 22.1 SPI introduction

The serial peripheral interface (SPI) allows half/ full-duplex, synchronous, serial communication with external devices. The interface can be configured as the master and in this case it provides the communication clock (SCK) to the external slave device. The interface is also capable of operating in multimaster configuration.

It may be used for a variety of purposes, including Simplex synchronous transfers on two lines with a possible bidirectional data line or reliable communication using CRC checking.

---

**Warning:** Since some SPI1 pins may be mapped onto some pins used by the JTAG interface (SPI1\_NSS onto JTDI, SPI1\_SCK onto JTDO and SPI1\_MISO onto NJTRST), you may either:

- map SPI1 onto other pins
- disable the JTAG and use the SWD interface prior to configuring the pins listed as SPI IOs (when debugging the application) or
- disable both JTAG/SWD interfaces (for standalone applications).

For more information on the configuration of the JTAG/SWD interface pins, please refer to [Section 5.3.2: I/O pin multiplexer and mapping](#).

---

## 22.2 SPI main features

### 22.2.1 SPI features

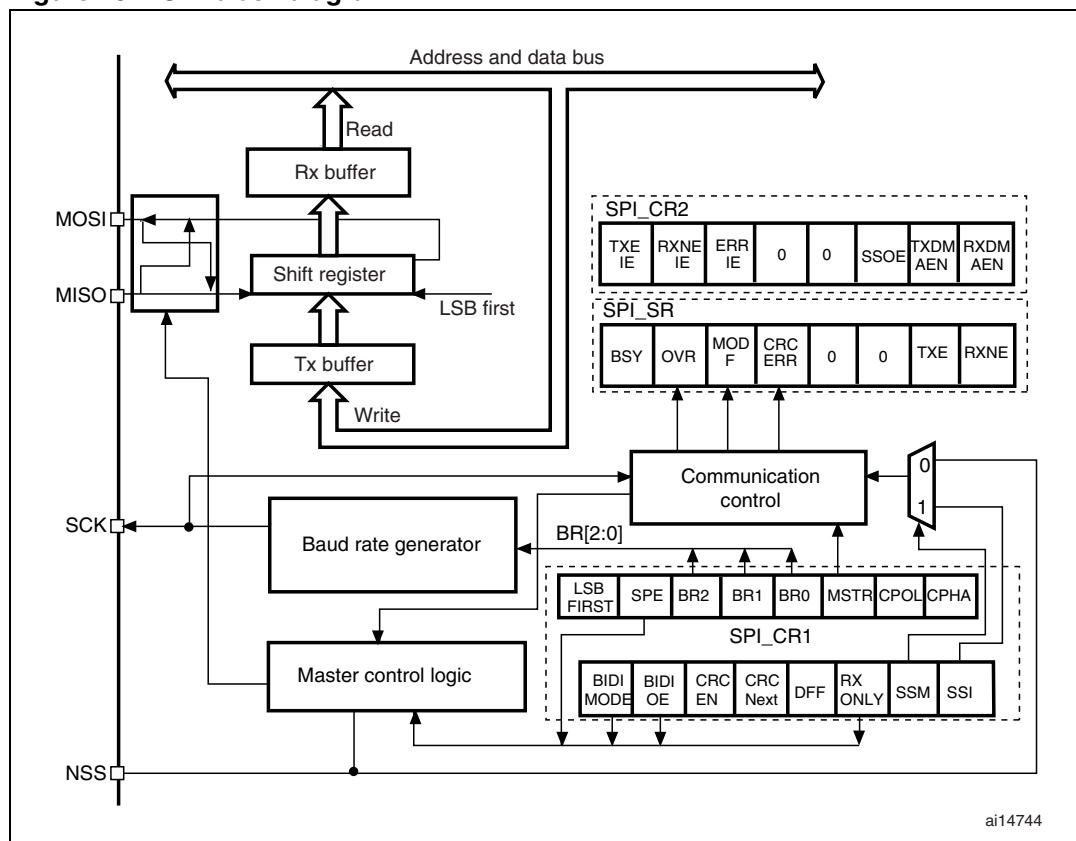

- Full-duplex synchronous transfers on three lines
- Simplex synchronous transfers on two lines with or without a bidirectional data line
- 8- or 16-bit transfer frame format selection
- Master or slave operation
- Multimaster mode capability
- 8 master mode baud rate prescalers ( $f_{PCLK}/2$  max.)
- Slave mode frequency ( $f_{PCLK}/2$  max)
- Faster communication for both master and slave
- NSS management by hardware or software for both master and slave: dynamic change of master/slave operations
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Dedicated transmission and reception flags with interrupt capability
- SPI bus busy status flag
- Hardware CRC feature for reliable communication:
  - CRC value can be transmitted as last byte in Tx mode
  - Automatic CRC error checking for last received byte
- Master mode fault, overrun and CRC error flags with interrupt capability
- 1-byte transmission and reception buffer with DMA capability: Tx and Rx requests

## 22.3 SPI functional description

### 22.3.1 General description

The block diagram of the SPI is shown in [Figure 167](#).

Figure 167. SPI block diagram

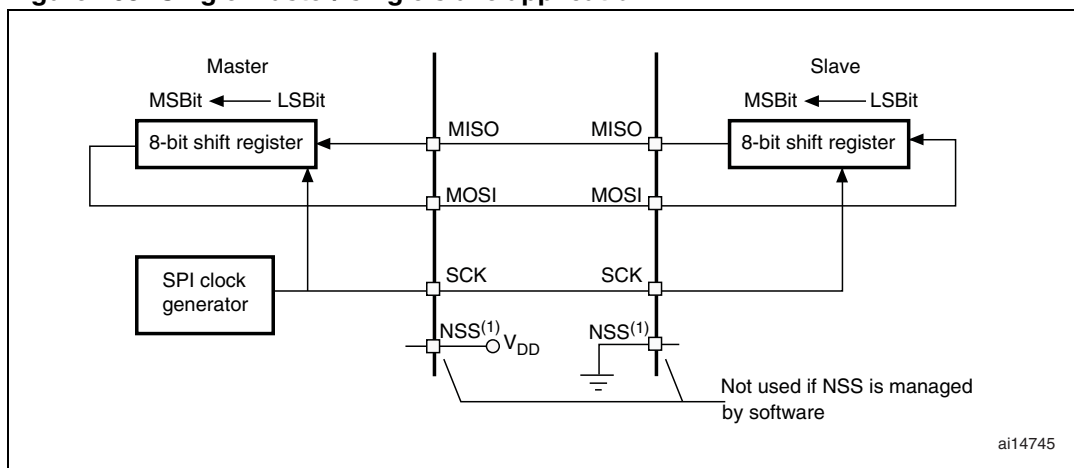

Usually, the SPI is connected to external devices through 4 pins:

- MISO: Master In / Slave Out data. This pin can be used to transmit data in slave mode and receive data in master mode.
- MOSI: Master Out / Slave In data. This pin can be used to transmit data in master mode and receive data in slave mode.
- SCK: Serial Clock output for SPI masters and input for SPI slaves.
- NSS: Slave select. This is an optional pin to select a slave device. This pin acts as a ‘chip select’ to let the SPI master communicate with slaves individually and to avoid contention on the data lines. Slave NSS inputs can be driven by standard IO ports on the master device. The NSS pin may also be used as an output if enabled (SSOE bit) and driven low if the SPI is in master configuration. In this manner, all NSS pins from devices connected to the Master NSS pin see a low level and become slaves when they are configured in NSS hardware mode. When configured in master mode with NSS configured as an input (MSTR=1 and SSOE=0) and if NSS is pulled low, the SPI enters the master mode fault state: the MSTR bit is automatically cleared and the device is configured in slave mode (refer to [Section 22.3.10: Error flags on page 505](#)).

A basic example of interconnections between a single master and a single slave is illustrated in [Figure 168](#).

Figure 168. Single master/ single slave application

1. Here, the NSS pin is configured as an input.

The MOSI pins are connected together and the MISO pins are connected together. In this way data is transferred serially between master and slave (most significant bit first).

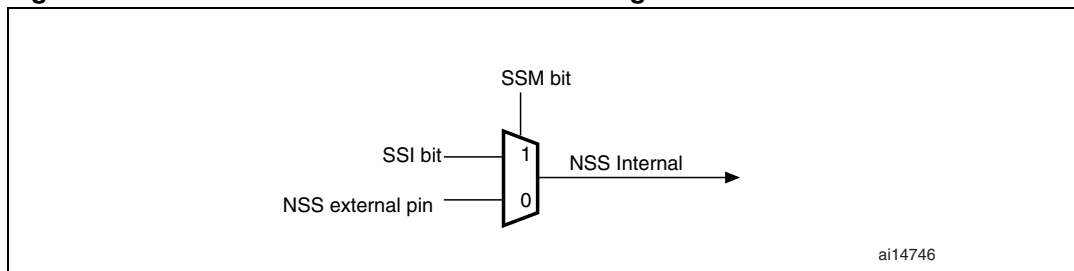

The communication is always initiated by the master. When the master device transmits data to a slave device via the MOSI pin, the slave device responds via the MISO pin. This implies full-duplex communication with both data out and data in synchronized with the same clock signal (which is provided by the master device via the SCK pin).

### Slave select (NSS) pin management

There are two NSS modes:

- Software NSS mode: this mode is enabled by setting the SSM bit in the SPI\_CR1 register (see [Figure 169](#)). In this mode, the external NSS pin is free for other application uses and the internal NSS signal level is driven by writing to the SSI bit in the SPI\_CR1 register.
- Hardware NSS mode: there are two cases:
  - NSS output is enabled: when the STM32L15xxx are operates as a Master and the NSS output is enabled through the SSOE bit in the SPI\_CR2 register, the NSS pin is driven low and all the NSS pins of devices connected to the Master NSS pin see a low level and become slaves when they are configured in NSS hardware mode. When an SPI wants to broadcast a message, it has to pull NSS low to inform all others that there is now a master for the bus. If it fails to pull NSS low, this means that there is another master communicating, and a Hard Fault error occurs.
  - NSS output is disabled: the multimaster capability is allowed.

Figure 169. Hardware/software slave select management

### Clock phase and clock polarity

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPI\_CR1 register. The CPOL (clock polarity) bit controls the steady state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA (clock phase) bit is set, the second edge on the SCK pin (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set) is the MSBit capture strobe. Data are latched on the occurrence of the second clock transition. If the CPHA bit is reset, the first edge on the SCK pin (falling edge if CPOL bit is set, rising edge if CPOL bit is reset) is the MSBit capture strobe. Data are latched on the occurrence of the first clock transition.

The combination of the CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.

*Figure 170*, shows an SPI transfer with the four combinations of the CPHA and CPOL bits. The diagram may be interpreted as a master or slave timing diagram where the SCK pin, the MISO pin, the MOSI pin are directly connected between the master and the slave device.

- Note:*
- 1 *Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit.*
  - 2 *Master and slave must be programmed with the same timing mode.*
  - 3 *The idle state of SCK must correspond to the polarity selected in the SPI\_CR1 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).*
  - 4 *The Data Frame Format (8- or 16-bit) is selected through the DFF bit in SPI\_CR1 register, and determines the data length during transmission/reception.*

Figure 170. Data clock timing diagram

1. These timings are shown with the LSBFIRST bit reset in the SPI\_CR1 register.

**Data frame format**

Data can be shifted out either MSB-first or LSB-first depending on the value of the LSBFIRST bit in the SPI\_CR1 Register.

Each data frame is 8 or 16 bits long depending on the size of the data programmed using the DFF bit in the SPI\_CR1 register. The selected data frame format is applicable for transmission and/or reception.

**22.3.2 Configuring the SPI in slave mode**

In the slave configuration, the serial clock is received on the SCK pin from the master device. The value set in the BR[2:0] bits in the SPI\_CR1 register, does not affect the data transfer rate.

*Note: It is recommended to enable the SPI slave before the master sends the clock. If not, undesired data transmission might occur. The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication. It is mandatory to have the polarity of the communication clock set to the steady state value before the slave and the master are enabled.*

Follow the procedure below to configure the SPI in slave mode:

### Procedure

1. Set the DFF bit to define 8- or 16-bit data frame format
2. Select the CPOL and CPHA bits to define one of the four relationships between the data transfer and the serial clock (see [Figure 170](#)). For correct data transfer, the CPOL and CPHA bits must be configured in the same way in the slave device and the master device.
3. The frame format (MSB-first or LSB-first depending on the value of the LSBFIRST bit in the SPI\_CR1 register) must be the same as the master device.
4. In Hardware mode (refer to [Slave select \(NSS\) pin management on page 488](#)), the NSS pin must be connected to a low level signal during the complete byte transmit sequence. In NSS software mode, set the SSM bit and clear the SSI bit in the SPI\_CR1 register.
5. Clear the MSTR bit and set the SPE bit (both in the SPI\_CR1 register) to assign the pins to alternate functions.

In this configuration the MOSI pin is a data input and the MISO pin is a data output.

### Transmit sequence

The data byte is parallel-loaded into the Tx buffer during a write cycle.

The transmit sequence begins when the slave device receives the clock signal and the most significant bit of the data on its MOSI pin. The remaining bits (the 7 bits in 8-bit data frame format, and the 15 bits in 16-bit data frame format) are loaded into the shift-register. The TXE flag in the SPI\_SR register is set on the transfer of data from the Tx Buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPI\_CR2 register is set.

### Receive sequence

For the receiver, when data transfer is complete:

- The Data in shift register is transferred to Rx Buffer and the RXNE flag (SPI\_SR register) is set
- An Interrupt is generated if the RXNEIE bit is set in the SPI\_CR2 register.

After the last sampling clock edge the RXNE bit is set, a copy of the data byte received in the shift register is moved to the Rx buffer. When the SPI\_DR register is read, the SPI peripheral returns this buffered value.

Clearing of the RXNE bit is performed by reading the SPI\_DR register.

### 22.3.3 Configuring the SPI in master mode

In the master configuration, the serial clock is generated on the SCK pin.

#### Procedure

1. Select the BR[2:0] bits to define the serial clock baud rate (see SPI\_CR1 register).
2. Select the CPOL and CPHA bits to define one of the four relationships between the data transfer and the serial clock (see [Figure 170](#)).
3. Set the DFF bit to define 8- or 16-bit data frame format
4. Configure the LSBFIRST bit in the SPI\_CR1 register to define the frame format.
5. If the NSS pin is required in input mode, in hardware mode, connect the NSS pin to a high-level signal during the complete byte transmit sequence. In NSS software mode, set the SSM and SSI bits in the SPI\_CR1 register. If the NSS pin is required in output mode, the SSOE bit only should be set.
6. The MSTR and SPE bits must be set (they remain set only if the NSS pin is connected to a high-level signal).

In this configuration the MOSI pin is a data output and the MISO pin is a data input.

#### Transmit sequence

The transmit sequence begins when a byte is written in the Tx Buffer.

The data byte is parallel-loaded into the shift register (from the internal bus) during the first bit transmission and then shifted out serially to the MOSI pin MSB first or LSB first depending on the LSBFIRST bit in the SPI\_CR1 register. The TXE flag is set on the transfer of data from the Tx Buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPI\_CR2 register is set.

#### Receive sequence

For the receiver, when data transfer is complete:

- The data in the shift register is transferred to the RX Buffer and the RXNE flag is set
- An interrupt is generated if the RXNEIE bit is set in the SPI\_CR2 register

At the last sampling clock edge the RXNE bit is set, a copy of the data byte received in the shift register is moved to the Rx buffer. When the SPI\_DR register is read, the SPI peripheral returns this buffered value.

Clearing the RXNE bit is performed by reading the SPI\_DR register.

A continuous transmit stream can be maintained if the next data to be transmitted is put in the Tx buffer once the transmission is started. Note that TXE flag should be '1 before any attempt to write the Tx buffer is made.

*Note:* In the NSS hardware mode, the slave's NSS input is controlled by the NSS pin or another GPIO pin that has to be controlled by software.

### 22.3.4 Configuring the SPI for Simplex communication

The SPI is capable of operating in simplex mode in 2 configurations.

- 1 clock and 1 bidirectional data wire
- 1 clock and 1 data wire (receive-only or transmit-only)

#### 1 clock and 1 bidirectional data wire (BIDIMODE=1)

This mode is enabled by setting the BIDIMODE bit in the SPI\_CR1 register. In this mode SCK is used for the clock and MOSI in master or MISO in slave mode is used for data communication. The transfer direction (Input/Output) is selected by the BIDIOE bit in the SPI\_CR1 register. When this bit is 1, the data line is output otherwise it is input.

#### 1 clock and 1 unidirectional data wire (BIDIMODE=0)

In this mode, the application can use the SPI either in transmit-only mode or in receive-only mode.

- Transmit-only mode is similar to full-duplex mode (BIDIMODE=0, RXONLY=0): the data are transmitted on the transmit pin (MOSI in master mode or MISO in slave mode) and the receive pin (MISO in master mode or MOSI in slave mode) can be used as a general-purpose IO. In this case, the application just needs to ignore the Rx buffer (if the data register is read, it does not contain the received value).
- In receive-only mode, the application can disable the SPI output function by setting the RXONLY bit in the SPI\_CR2 register. In this case, it frees the transmit IO pin (MOSI in master mode or MISO in slave mode), so it can be used for other purposes.

To start the communication in receive-only mode, configure and enable the SPI:

- In master mode, the communication starts immediately and stops when the SPE bit is cleared and the current reception stops. There is no need to read the BSY flag in this mode. It is always set when an SPI communication is ongoing.
- In slave mode, the SPI continues to receive as long as the NSS is pulled down (or the SSI bit is cleared in NSS software mode) and the SCK is running.

### 22.3.5 Data transmission and reception procedures

#### Rx and Tx buffers

In reception, data are received and then stored into an internal Rx buffer while In transmission, data are first stored into an internal Tx buffer before being transmitted.

A read access of the SPI\_DR register returns the Rx buffered value whereas a write access to the SPI\_DR stores the written data into the Tx buffer.

**Start sequence in master mode**

- In full-duplex (BIDIMODE=0 and RXONLY=0)
  - The sequence begins when data are written into the SPI\_DR register (Tx buffer).
  - The data are then parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission and then shifted out serially to the MOSI pin.
  - At the same time, the received data on the MISO pin is shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
- In unidirectional receive-only mode (BIDIMODE=0 and RXONLY=1)
  - The sequence begins as soon as SPE=1
  - Only the receiver is activated and the received data on the MISO pin are shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
- In bidirectional mode, when transmitting (BIDIMODE=1 and BIDIOE=1)
  - The sequence begins when data are written into the SPI\_DR register (Tx buffer).
  - The data are then parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission and then shifted out serially to the MOSI pin.
  - No data are received.
- In bidirectional mode, when receiving (BIDIMODE=1 and BIDIOE=0)
  - The sequence begins as soon as SPE=1 and BIDIOE=0.
  - The received data on the MOSI pin are shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
  - The transmitter is not activated and no data are shifted out serially to the MOSI pin.

**Start sequence in slave mode**

- In full-duplex mode (BIDIMODE=0 and RXONLY=0)
  - The sequence begins when the slave device receives the clock signal and the first bit of the data on its MOSI pin. The 7 remaining bits are loaded into the shift register.
  - At the same time, the data are parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission, and then shifted out serially to the MISO pin. The software must have written the data to be sent before the SPI master device initiates the transfer.
- In unidirectional receive-only mode (BIDIMODE=0 and RXONLY=1)
  - The sequence begins when the slave device receives the clock signal and the first bit of the data on its MOSI pin. The 7 remaining bits are loaded into the shift register.
  - The transmitter is not activated and no data are shifted out serially to the MISO pin.

- In bidirectional mode, when transmitting (BIDIMODE=1 and BIDIOE=1)
  - The sequence begins when the slave device receives the clock signal and the first bit in the Tx buffer is transmitted on the MISO pin.
  - The data are then parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission and then shifted out serially to the MISO pin. The software must have written the data to be sent before the SPI master device initiates the transfer.
  - No data are received.
- In bidirectional mode, when receiving (BIDIMODE=1 and BIDIOE=0)
  - The sequence begins when the slave device receives the clock signal and the first bit of the data on its MISO pin.
  - The received data on the MISO pin are shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
  - The transmitter is not activated and no data are shifted out serially to the MISO pin.

### Handling data transmission and reception

The TXE flag (Tx buffer empty) is set when the data are transferred from the Tx buffer to the shift register. It indicates that the internal Tx buffer is ready to be loaded with the next data. An interrupt can be generated if the TXEIE bit in the SPI\_CR2 register is set. Clearing the TXE bit is performed by writing to the SPI\_DR register.

*Note: The software must ensure that the TXE flag is set to 1 before attempting to write to the Tx buffer. Otherwise, it overwrites the data previously written to the Tx buffer.*

The RXNE flag (Rx buffer not empty) is set on the last sampling clock edge, when the data are transferred from the shift register to the Rx buffer. It indicates that data are ready to be read from the SPI\_DR register. An interrupt can be generated if the RXNEIE bit in the SPI\_CR2 register is set. Clearing the RXNE bit is performed by reading the SPI\_DR register.

For some configurations, the BSY flag can be used during the last data transfer to wait until the completion of the transfer.

### Full-duplex transmit and receive procedure in master or slave mode (BIDIMODE=0 and RXONLY=0)

The software has to follow this procedure to transmit and receive data (see [Figure 171](#) and [Figure 172](#)):

1. Enable the SPI by setting the SPE bit to 1.
2. Write the first data item to be transmitted into the SPI\_DR register (this clears the TXE flag).
3. Wait until TXE=1 and write the second data item to be transmitted. Then wait until RXNE=1 and read the SPI\_DR to get the first received data item (this clears the RXNE bit). Repeat this operation for each data item to be transmitted/received until the n-1 received data.
4. Wait until RXNE=1 and read the last received data.
5. Wait until TXE=1 and then wait until BSY=0 before disabling the SPI.

This procedure can also be implemented using dedicated interrupt subroutines launched at each rising edges of the RXNE or TXE flag.

**Figure 171. TXE/RXNE/BSY behavior in Master / full-duplex mode (BIDIMODE=0 and RXONLY=0) in the case of continuous transfers**

**Figure 172. TXE/RXNE/BSY behavior in Slave / full-duplex mode (BIDIMODE=0, RXONLY=0) in the case of continuous transfers**

**Transmit-only procedure (BIDIMODE=0 RXONLY=0)**

In this mode, the procedure can be reduced as described below and the BSY bit can be used to wait until the completion of the transmission (see *Figure 173* and *Figure 174*).

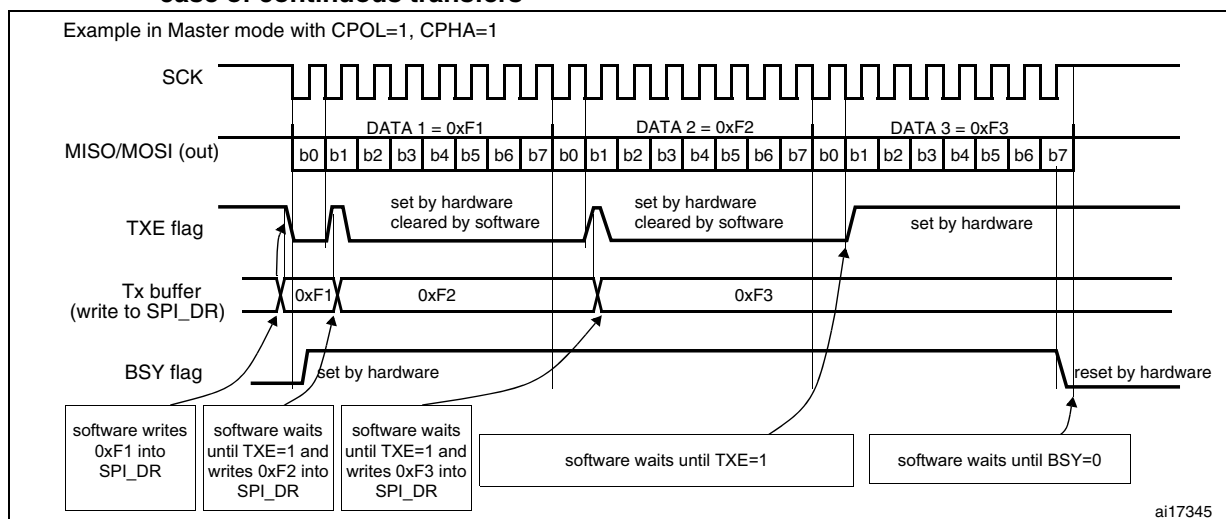

1. Enable the SPI by setting the SPE bit to 1.
2. Write the first data item to send into the SPI\_DR register (this clears the TXE bit).
3. Wait until TXE=1 and write the next data item to be transmitted. Repeat this step for each data item to be transmitted.
4. After writing the last data item into the SPI\_DR register, wait until TXE=1, then wait until BSY=0, this indicates that the transmission of the last data is complete.

This procedure can be also implemented using dedicated interrupt subroutines launched at each rising edge of the TXE flag.

*Note:* 1 During discontinuous communications, there is a 2 APB clock period delay between the write operation to SPI\_DR and the BSY bit setting. As a consequence, in transmit-only mode, it is mandatory to wait first until TXE is set and then until BSY is cleared after writing the last data.

2 After transmitting two data items in transmit-only mode, the OVR flag is set in the SPI\_SR register since the received data are never read.

**Figure 173. TXE/BSY behavior in Master transmit-only mode (BIDIMODE=0 and RXONLY=0) in the case of continuous transfers**

**Figure 174. TXE/BSY in Slave transmit-only mode (BIDIMODE=0 and RXONLY=0) in the case of continuous transfers**

**Bidirectional transmit procedure (BIDIMODE=1 and BIDIOE=1)**

In this mode, the procedure is similar to the procedure in Transmit-only mode except that the BIDIMODE and BIDIOE bits both have to be set in the SPI\_CR2 register before enabling the SPI.

**Unidirectional receive-only procedure (BIDIMODE=0 and RXONLY=1)**

In this mode, the procedure can be reduced as described below (see [Figure 175](#)):

1. Set the RXONLY bit in the SPI\_CR2 register.
2. Enable the SPI by setting the SPE bit to 1:
  - a) In master mode, this immediately activates the generation of the SCK clock, and data are serially received until the SPI is disabled (SPE=0).
  - b) In slave mode, data are received when the SPI master device drives NSS low and generates the SCK clock.
3. Wait until RXNE=1 and read the SPI\_DR register to get the received data (this clears the RXNE bit). Repeat this operation for each data item to be received.

This procedure can also be implemented using dedicated interrupt subroutines launched at each rising edge of the RXNE flag.

*Note:* If it is required to disable the SPI after the last transfer, follow the recommendation described in [Section 22.3.8: Disabling the SPI on page 503](#).

**Figure 175. RXNE behavior in receive-only mode (BIDIRMODE=0 and RXONLY=1) in the case of continuous transfers**

### Bidirectional receive procedure (BIDIMODE=1 and BIDIOE=0)

In this mode, the procedure is similar to the Receive-only mode procedure except that the BIDIMODE bit has to be set and the BIDIOE bit cleared in the SPI\_CR2 register before enabling the SPI.

### Continuous and discontinuous transfers

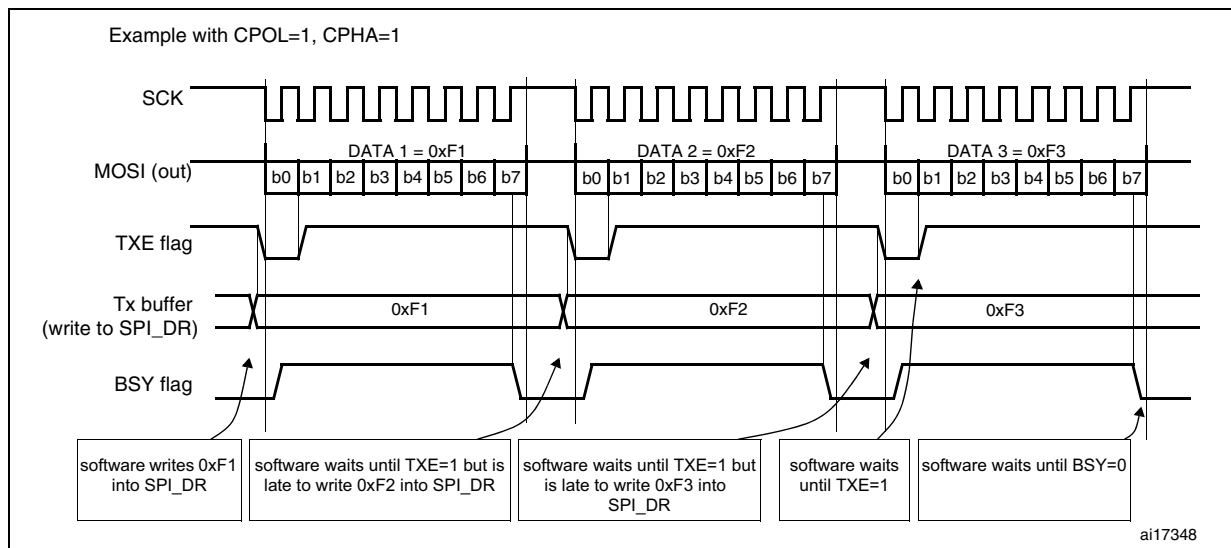

When transmitting data in master mode, if the software is fast enough to detect each rising edge of TXE (or TXE interrupt) and to immediately write to the SPI\_DR register before the ongoing data transfer is complete, the communication is said to be continuous. In this case, there is no discontinuity in the generation of the SPI clock between each data item and the BSY bit is never cleared between each data transfer.

On the contrary, if the software is not fast enough, this can lead to some discontinuities in the communication. In this case, the BSY bit is cleared between each data transmission (see [Figure 176](#)).

In Master receive-only mode (RXONLY=1), the communication is always continuous and the BSY flag is always read at 1.

In slave mode, the continuity of the communication is decided by the SPI master device. In any case, even if the communication is continuous, the BSY flag goes low between each transfer for a minimum duration of one SPI clock cycle (see [Figure 174](#)).

**Figure 176. TXE/BSY behavior when transmitting (BIDIRMODE=0 and RXONLY=0) in the case of discontinuous transfers**

### 22.3.6 CRC calculation

A CRC calculator has been implemented for communication reliability. Separate CRC calculators are implemented for transmitted data and received data. The CRC is calculated using a programmable polynomial serially on each bit. It is calculated on the sampling clock edge defined by the CPHA and CPOL bits in the SPI\_CR1 register.

*Note:* This SPI offers two kinds of CRC calculation standard which depend directly on the data frame format selected for the transmission and/or reception: 8-bit data (CR8) and 16-bit data (CRC16).

CRC calculation is enabled by setting the CRCEN bit in the SPI\_CR1 register. This action resets the CRC registers (SPI\_RXCRCR and SPI\_TXCRCR). In full duplex or transmitter only mode, when the transfers are managed by the software (CPU mode), it is necessary to write the bit CRCNEXT immediately after the last data to be transferred is written to the SPI\_DR. At the end of this last data transfer, the SPI\_TXCRCR value is transmitted.

In receive only mode and when the transfers are managed by software (CPU mode), it is necessary to write the CRCNEXT bit after the second last data has been received. The CRC is received just after the last data reception and the CRC check is then performed.

At the end of data and CRC transfers, the CRCERR flag in the SPI\_SR register is set if corruption occurs during the transfer.

If data are present in the TX buffer, the CRC value is transmitted only after the transmission of the data byte. During CRC transmission, the CRC calculator is switched off and the register value remains unchanged.

*Note:* Please refer to the product specifications for availability of this feature.

SPI communication using CRC is possible through the following procedure:

- Program the CPOL, CPHA, LSBFirst, BR, SSM, SSI and MSTR values
- Program the polynomial in the SPI\_CRCPR register
- Enable the CRC calculation by setting the CRCEN bit in the SPI\_CR1 register. This also clears the SPI\_RXCRCR and SPI\_TXCRCR registers
- Enable the SPI by setting the SPE bit in the SPI\_CR1 register
- Start the communication and sustain the communication until all but one byte or half-word have been transmitted or received.
- In full duplex or transmitter-only mode, when the transfers are managed by software, on writing the last byte or half word to the TX buffer, set the CRCNEXT bit in the SPI\_CR1 register to indicate that after the transmission of the last byte, the CRC, is to be transmitted. In receiver only mode, set the CRCNEXT bit just after the reception of the second last data in order to prepare the SPI to enter the CRC phase at the end of the reception of the last data. CRC calculation is frozen during the CRC transfer.
- After the transfer of the last byte or half word, the SPI enters the CRC transfer and check phase. In full duplex mode or receiver-only mode, the received CRC is compared to the SPI\_RXCRCR value. If the value does not match, the CRCERR flag in SPI\_SR is set and an interrupt can be generated when the ERRIE bit in the SPI\_CR2 register is set.

*Note:* When the SPI is in slave mode, be careful to enable CRC calculation only when the clock is stable, that is, when the clock is in the steady state. If not, a wrong CRC calculation may be done. In fact, the CRC is sensitive to the SCK slave input clock as soon as CRCEN is set, and this, whatever the value of the SPE bit.

*With high bitrate frequencies, be careful when transmitting the CRC. As the number of used CPU cycles has to be as low as possible in the CRC transfer phase, it is forbidden to call software functions in the CRC transmission sequence to avoid errors in the last data and CRC reception. In fact, CRCNEXT bit has to be written before the end of the transmission/reception of the last data.*

*For high bit rate frequencies, it is advised to use the DMA mode to avoid the degradation of the SPI speed performance due to CPU accesses impacting the SPI bandwidth.*

*When the STM32L15xx areis configured as slaves and the NSS hardware mode is used, the NSS pin needs to be kept low between the data phase and the CRC phase.*

When the SPI is configured in slave mode with the CRC feature enabled, CRC calculation takes place even if a high level is applied on the NSS pin. This may happen for example in case of a multislave environment where the communication master addresses slaves alternately.

Between a slave deselection (high level on NSS) and a new slave selection (low level on NSS), the CRC value should be cleared on both master and slave sides in order to resynchronize the master and slave for their respective CRC calculation.

To clear the CRC, follow the procedure below:

1. Disable SPI (SPE = 0)
2. Clear the CRCEN bit
3. Set the CRCEN bit
4. Enable the SPI (SPE = 1)

### 22.3.7 Status flags

Three status flags are provided for the application to completely monitor the state of the SPI bus.

#### Tx buffer empty flag (TXE)

When it is set, this flag indicates that the Tx buffer is empty and the next data to be transmitted can be loaded into the buffer. The TXE flag is cleared when writing to the SPI\_DR register.

#### Rx buffer not empty (RXNE)

When set, this flag indicates that there are valid received data in the Rx buffer. It is cleared when SPI\_DR is read.

#### BUSY flag

This BSY flag is set and cleared by hardware (writing to this flag has no effect). The BSY flag indicates the state of the communication layer of the SPI.

When BSY is set, it indicates that the SPI is busy communicating. There is one exception in master mode / bidirectional receive mode (MSTR=1 and BDM=1 and BDOE=0) where the BSY flag is kept low during reception.

The BSY flag is useful to detect the end of a transfer if the software wants to disable the SPI and enter Halt mode (or disable the peripheral clock). This avoids corrupting the last transfer. For this, the procedure described below must be strictly respected.

The BSY flag is also useful to avoid write collisions in a multimaster system.

The BSY flag is set when a transfer starts, with the exception of master mode / bidirectional receive mode (MSTR=1 and BDM=1 and BDOE=0).

It is cleared:

- when a transfer is finished (except in master mode if the communication is continuous)
- when the SPI is disabled
- when a master mode fault occurs (MODF=1)

When communication is not continuous, the BSY flag is low between each communication.

When communication is continuous:

- in master mode, the BSY flag is kept high during all the transfers
- in slave mode, the BSY flag goes low for one SPI clock cycle between each transfer

*Note: Do not use the BSY flag to handle each data transmission or reception. It is better to use the TXE and RXNE flags instead.*

### 22.3.8 Disabling the SPI

When a transfer is terminated, the application can stop the communication by disabling the SPI peripheral. This is done by clearing the SPE bit.

For some configurations, disabling the SPI and entering the Halt mode while a transfer is ongoing can cause the current transfer to be corrupted and/or the BSY flag might become unreliable.

To avoid any of those effects, it is recommended to respect the following procedure when disabling the SPI:

#### **In master or slave full-duplex mode (BIDIMODE=0, RXONLY=0)**

1. Wait until RXNE=1 to receive the last data
2. Wait until TXE=1
3. Then wait until BSY=0
4. Disable the SPI (SPE=0) and, eventually, enter the Halt mode (or disable the peripheral clock)

#### **In master or slave unidirectional transmit-only mode (BIDIMODE=0, RXONLY=0) or bidirectional transmit mode (BIDIMODE=1, BIDIOE=1)**

After the last data is written into the SPI\_DR register:

1. Wait until TXE=1
2. Then wait until BSY=0
3. Disable the SPI (SPE=0) and, eventually, enter the Halt mode (or disable the peripheral clock)

#### **In master unidirectional receive-only mode (MSTR=1, BIDIMODE=0, RXONLY=1) or bidirectional receive mode (MSTR=1, BIDIMODE=1, BIDIOE=0)**

This case must be managed in a particular way to ensure that the SPI does not initiate a new transfer:

1. Wait for the second to last occurrence of RXNE=1 (n-1)
2. Then wait for one SPI clock cycle (using a software loop) before disabling the SPI (SPE=0)
3. Then wait for the last RXNE=1 before entering the Halt mode (or disabling the peripheral clock)

*Note:* In master bidirectional receive mode (MSTR=1 and BDM=1 and BDOE=0), the BSY flag is kept low during transfers.

#### **In slave receive-only mode (MSTR=0, BIDIMODE=0, RXONLY=1) or bidirectional receive mode (MSTR=0, BIDIMODE=1, BIDIOE=0)**

1. You can disable the SPI (write SPE=1) at any time: the current transfer will complete before the SPI is effectively disabled
2. Then, if you want to enter the Halt mode, you must first wait until BSY = 0 before entering the Halt mode (or disabling the peripheral clock)

### 22.3.9 SPI communication using DMA (direct memory addressing)

To operate at its maximum speed, the SPI needs to be fed with the data for transmission and the data received on the Rx buffer should be read to avoid overrun. To facilitate the transfers, the SPI features a DMA capability implementing a simple request/acknowledge protocol.

A DMA access is requested when the enable bit in the SPI\_CR2 register is enabled. Separate requests must be issued to the Tx and Rx buffers (see [Figure 177](#) and [Figure 178](#)):

- In transmission, a DMA request is issued each time TXE is set to 1. The DMA then writes to the SPI\_DR register (this clears the TXE flag).
- In reception, a DMA request is issued each time RXNE is set to 1. The DMA then reads the SPI\_DR register (this clears the RXNE flag).

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel. In this case, the OVR flag is set because the data received are not read.

When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.

In transmission mode, when the DMA has written all the data to be transmitted (flag TCIF is set in the DMA\_ISR register), the BSY flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or entering the Stop mode. The software must first wait until TXE=1 and then until BSY=0.

*Note:* During discontinuous communications, there is a 2 APB clock period delay between the write operation to SPI\_DR and the BSY bit setting. As a consequence, it is mandatory to wait first until TXE=1 and then until BSY=0 after writing the last data.

**Figure 177. Transmission using DMA**

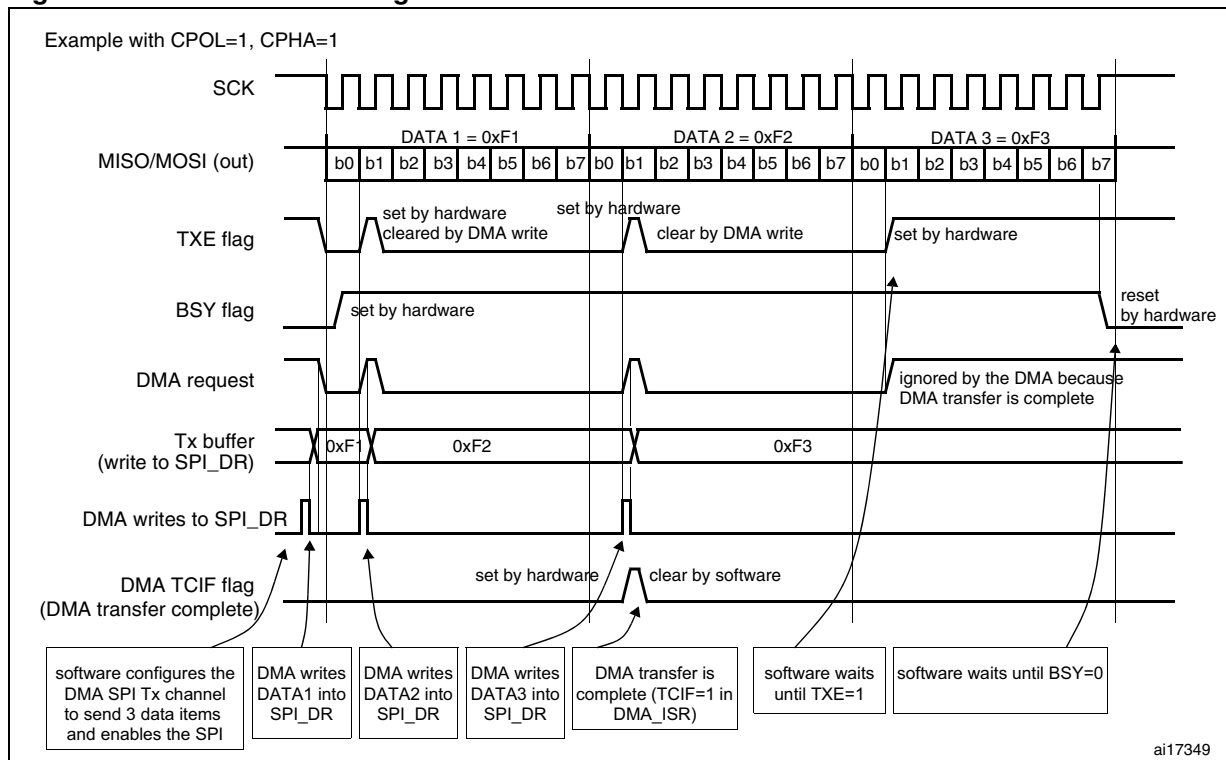

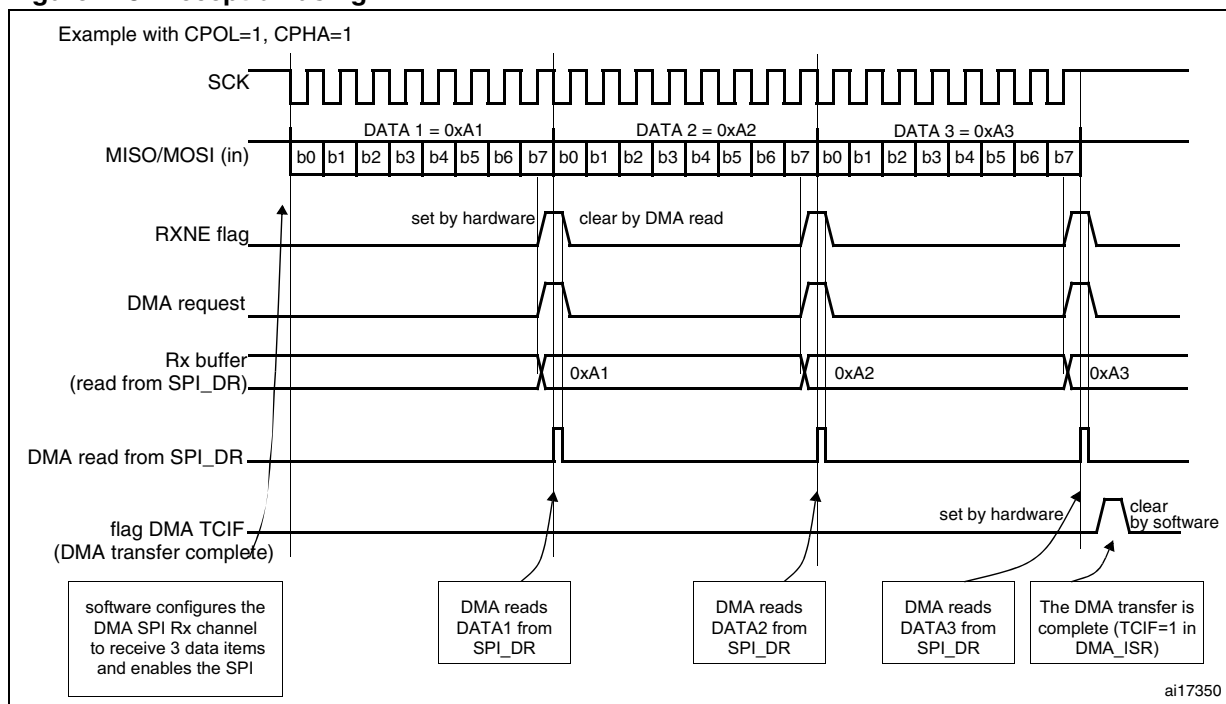

Figure 178. Reception using DMA

### DMA capability with CRC

When SPI communication is enabled with CRC communication and DMA mode, the transmission and reception of the CRC at the end of communication are automatic i.e. without using the bit CRCNEXT. After the CRC reception, the CRC must be read in the SPI\_DR register in order to clear the RXNE flag.

At the end of data and CRC transfers, the CRCERR flag in SPI\_SR is set if corruption occurs during the transfer.

## 22.3.10 Error flags

### Master mode fault (MODF)

Master mode fault occurs when the master device has its NSS pin pulled low (in NSS hardware mode) or SSI bit low (in NSS software mode), this automatically sets the MODF bit. Master mode fault affects the SPI peripheral in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the ERRIE bit is set.
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MSTR bit is cleared, thus forcing the device into slave mode.

Use the following software sequence to clear the MODF bit:

1. Make a read or write access to the SPI\_SR register while the MODF bit is set.
2. Then write to the SPI\_CR1 register.

To avoid any multiple slave conflicts in a system comprising several MCUs, the NSS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits can be restored to their original state after this clearing sequence.

As a security, hardware does not allow the setting of the SPE and MSTR bits while the MODF bit is set.

In a slave device the MODF bit cannot be set. However, in a multimaster configuration, the device can be in slave mode with this MODF bit set. In this case, the MODF bit indicates that there might have been a multimaster conflict for system control. An interrupt routine can be used to recover cleanly from this state by performing a reset or returning to a default state.

**Overrun condition**

An overrun condition occurs when the master device has sent data bytes and the slave device has not cleared the RXNE bit resulting from the previous data byte transmitted. When an overrun condition occurs:

- the OVR bit is set and an interrupt is generated if the ERRIE bit is set.

In this case, the receiver buffer contents will not be updated with the newly received data from the master device. A read from the SPI\_DR register returns this byte. All other subsequently transmitted bytes are lost.

Clearing the OVR bit is done by a read from the SPI\_DR register followed by a read access to the SPI\_SR register.

**CRC error**

This flag is used to verify the validity of the value received when the CRCEN bit in the SPI\_CR1 register is set. The CRCERR flag in the SPI\_SR register is set if the value received in the shift register does not match the receiver SPI\_RXCR value.

**22.3.11 SPI interrupts**

**Table 81. SPI interrupt requests**

Interrupt event	Event flag	Enable Control bit
Transmit buffer empty flag	TXE	TXEIE
Receive buffer not empty flag	RXNE	RXNEIE
Master Mode fault event	MODF	ERRIE
Overrun error	OVR	
CRC error flag	CRCERR	

is 32-bit wide

## 22.4 SPI registers

Refer to for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 22.4.1 SPI control register 1 (SPI\_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BIDI MODE	BIDI OE	CRC EN	CRC NEXT	DFF	RX ONLY	SSM	SSI	LSB FIRST	SPE	BR [2:0]			MSTR	CPOL	CPHA
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 15 **BIDIMODE**: Bidirectional data mode enable  
 0: 2-line unidirectional data mode selected  
 1: 1-line bidirectional data mode selected

Bit 14 **BIDIOE**: Output enable in bidirectional mode  
 This bit combined with the BIDImode bit selects the direction of transfer in bidirectional mode  
 0: Output disabled (receive-only mode)  
 1: Output enabled (transmit-only mode)  
*Note: In master mode, the MOSI pin is used and in slave mode, the MISO pin is used.*

Bit 13 **CRCEN**: Hardware CRC calculation enable  
 0: CRC calculation disabled  
 1: CRC calculation Enabled  
*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation*

Bit 12 **CRCNEXT**: CRC transfer next  
 0: Data phase (no CRC phase)  
 1: Next transfer is CRC (CRC phase)  
*Note: This bit has to be written as soon as the last data is written to the SPI\_DR register when the SPI is configured in full duplex or transmitter only modes. It has to be set after the second last data reception when it is configured in receiver only mode. This bit should be kept cleared when the transfers are managed by DMA.*

Bit 11 **DFF**: Data frame format  
 0: 8-bit data frame format is selected for transmission/reception  
 1: 16-bit data frame format is selected for transmission/reception  
*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation*

Bit 10 **RXONLY**: Receive only  
 This bit combined with the BIDImode bit selects the direction of transfer in 2-line unidirectional mode. This bit is also useful in a multislave system in which this particular slave is not accessed, the output from the accessed slave is not corrupted.  
 0: Full duplex (Transmit and receive)  
 1: Output disabled (Receive-only mode)

Bit 9 **SSM**: Software slave management  
 When the SSM bit is set, the NSS pin input is replaced with the value from the SSI bit.  
 0: Software slave management disabled  
 1: Software slave management enabled

Bit 8 **SSI**: Internal slave select

This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the NSS pin and the IO value of the NSS pin is ignored.

Bit 7 **LSBFIRST**: Frame format

0: MSB transmitted first  
1: LSB transmitted first

*Note: This bit should not be changed when communication is ongoing.*

Bit 6 **SPE**: SPI enable

0: Peripheral disabled  
1: Peripheral enabled

*Note: When disabling the SPI, follow the procedure described in [Section 22.3.8: Disabling the SPI](#).*

Bits 5:3 **BR[2:0]**: Baud rate control

000:  $f_{PCLK}/2$   
001:  $f_{PCLK}/4$   
010:  $f_{PCLK}/8$   
011:  $f_{PCLK}/16$   
100:  $f_{PCLK}/32$   
101:  $f_{PCLK}/64$   
110:  $f_{PCLK}/128$   
111:  $f_{PCLK}/256$

*Note: These bits should not be changed when communication is ongoing.*

Bit 2 **MSTR**: Master selection

0: Slave configuration  
1: Master configuration

*Note: This bit should not be changed when communication is ongoing.*

Bit1 **CPOL**: Clock polarity

0: CK to 0 when idle  
1: CK to 1 when idle

*Note: This bit should not be changed when communication is ongoing.*

Bit 0 **CPHA**: Clock phase

0: The first clock transition is the first data capture edge  
1: The second clock transition is the first data capture edge

*Note: This bit should not be changed when communication is ongoing.*

### 22.4.2 SPI control register 2 (SPI\_CR2)

Address offset: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								TXEIE	RXNEIE	ERRIE	Res.	Res.	SSOE	TXDMAEN	RXDMAEN
								rw	rw	rw			rw	rw	rw

Bits 15:8 Reserved. Forced to 0 by hardware.

Bit 7 **TXEIE**: Tx buffer empty interrupt enable

0: TXE interrupt masked

1: TXE interrupt not masked. Used to generate an interrupt request when the TXE flag is set.

Bit 6 **RXNEIE**: RX buffer not empty interrupt enable

0: RXNE interrupt masked

1: RXNE interrupt not masked. Used to generate an interrupt request when the RXNE flag is set.

Bit 5 **ERRIE**: Error interrupt enable

This bit controls the generation of an interrupt when an error condition occurs (CRCERR, OVR, MODF in SPI mode).

0: Error interrupt is masked

1: Error interrupt is enabled

Bits 4:3 Reserved. Forced to 0 by hardware.

Bit 2 **SSOE**: SS output enable

0: SS output is disabled in master mode and the cell can work in multimaster configuration

1: SS output is enabled in master mode and when the cell is enabled. The cell cannot work in a multimaster environment.

Bit 1 **TXDMAEN**: Tx buffer DMA enable

When this bit is set, the DMA request is made whenever the TXE flag is set.

0: Tx buffer DMA disabled

1: Tx buffer DMA enabled

Bit 0 **RXDMAEN**: Rx buffer DMA enable

When this bit is set, the DMA request is made whenever the RXNE flag is set.

0: Rx buffer DMA disabled

1: Rx buffer DMA enabled

### 22.4.3 SPI status register (SPI\_SR)

Address offset: 0x08

Reset value: 0x0002

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								BSY	OVR	MODF	CRC ERR	Reserved		TXE	RXNE
								r	r	r	rc_w0			r	r

Bits 15:8 Reserved. Forced to 0 by hardware.

Bit 7 **BSY**: Busy flag

0: SPI not busy

1: SPI is busy in communication or Tx buffer is not empty

This flag is set and cleared by hardware.

*Note: BSY flag must be used with caution: refer to [Section 22.3.7: Status flags](#) and [Section 22.3.8: Disabling the SPI](#).*

Bit 6 **OVR**: Overrun flag

0: No overrun occurred

1: Overrun occurred

This flag is set by hardware and reset by a software sequence.

Bit 5 **MODF**: Mode fault

0: No mode fault occurred

1: Mode fault occurred

This flag is set by hardware and reset by a software sequence. Refer to [Section 22.3.10 on page 505](#) for the software sequence.

Bit 4 **CRCERR**: CRC error flag

0: CRC value received matches the SPI\_RXCRCR value

1: CRC value received does not match the SPI\_RXCRCR value

This flag is set by hardware and cleared by software writing 0.

Bits 3:2 Reserved

Bit 1 **TXE**: Transmit buffer empty

0: Tx buffer not empty

1: Tx buffer empty

Bit 0 **RXNE**: Receive buffer not empty

0: Rx buffer empty

1: Rx buffer not empty

### 22.4.4 SPI data register (SPI\_DR)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **DR[15:0]**: Data register

Data received or to be transmitted.

The data register is split into 2 buffers - one for writing (Transmit Buffer) and another one for reading (Receive buffer). A write to the data register will write into the Tx buffer and a read from the data register will return the value held in the Rx buffer.

**Notes for the SPI mode:**

*Depending on the data frame format selection bit (DFF in SPI\_CR1 register), the data sent or received is either 8-bit or 16-bit. This selection has to be made before enabling the SPI to ensure correct operation.*

*For an 8-bit data frame, the buffers are 8-bit and only the LSB of the register (SPI\_DR[7:0]) is used for transmission/reception. When in reception mode, the MSB of the register (SPI\_DR[15:8]) is forced to 0.*

*For a 16-bit data frame, the buffers are 16-bit and the entire register, SPI\_DR[15:0] is used for transmission/reception.*

### 22.4.5 SPI CRC polynomial register (SPI\_CRCPR)

Address offset: 0x10

Reset value: 0x0007

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRCPOLY[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **CRCPOLY[15:0]**: CRC polynomial register

This register contains the polynomial for the CRC calculation.

The CRC polynomial (0007h) is the reset value of this register. Another polynomial can be configured as required.

### 22.4.6 SPI RX CRC register (SPI\_RXCRCR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXCRC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 15:0 **RXCRC[15:0]**: Rx CRC register

When CRC calculation is enabled, the RxCRC[15:0] bits contain the computed CRC value of the subsequently received bytes. This register is reset when the CRCEN bit in SPI\_CR1 register is written to 1. The CRC is calculated serially using the polynomial programmed in the SPI\_CRCPR register.

Only the 8 LSB bits are considered when the data frame format is set to be 8-bit data (DFF bit of SPI\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit data frame format is selected (DFF bit of the SPI\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY Flag is set could return an incorrect value.*

### 22.4.7 SPI TX CRC register (SPI\_TXCRCR)

Address offset: 0x18

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TXCRC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 15:0 **TXCRC[15:0]**: Tx CRC register

When CRC calculation is enabled, the TxCRC[7:0] bits contain the computed CRC value of the subsequently transmitted bytes. This register is reset when the CRCEN bit of SPI\_CR1 is written to 1. The CRC is calculated serially using the polynomial programmed in the SPI\_CRCPR register.

Only the 8 LSB bits are considered when the data frame format is set to be 8-bit data (DFF bit of SPI\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit data frame format is selected (DFF bit of the SPI\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY flag is set could return an incorrect value.*

### 22.4.8 SPI register map

The table provides shows the SPI register map and reset values.

Table 82. SPI register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Table 1 on page 32](#) for the register boundary addresses.

## 23 Universal synchronous asynchronous receiver transmitter (USART)

### 23.1 USART introduction

The universal synchronous asynchronous receiver transmitter (USART) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The USART offers a very wide range of baud rates using a fractional baud rate generator.

It supports synchronous one-way communication and half-duplex single wire communication. It also supports the LIN (local interconnection network), Smartcard Protocol and IrDA (infrared data association) SIR ENDEC specifications, and modem operations (CTS/RTS). It allows multiprocessor communication.

High speed data communication is possible by using the DMA for multibuffer configuration.

### 23.2 USART main features

- Full duplex, asynchronous communications
- NRZ standard format (Mark/Space)
- Configurable oversampling method by 16 or by 8 to give flexibility between speed and clock tolerance
- Fractional baud rate generator systems
  - A common programmable transmit and receive baud rate of up to 4 Mbit/s when the APB frequency is 32 MHz and oversampling is by 8
- Programmable data word length (8 or 9 bits)
- Configurable stop bits - support for 1 or 2 stop bits
- LIN Master Synchronous Break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
- Transmitter clock output for synchronous transmission
- IrDA SIR encoder decoder
  - Support for 3/16 bit duration for normal mode
- Smartcard emulation capability
  - The Smartcard interface supports the asynchronous protocol Smartcards as defined in the ISO 7816-3 standards
  - 0.5, 1.5 stop bits for Smartcard operation
- Single-wire half-duplex communication
- Configurable multibuffer communication using DMA (direct memory access)
  - Buffering of received/transmitted bytes in reserved SRAM using centralized DMA
- Separate enable bits for transmitter and receiver

- Transfer detection flags:
  - Receive buffer full
  - Transmit buffer empty
  - End of transmission flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Four error detection flags:
  - Overrun error
  - Noise detection
  - Frame error
  - Parity error
- Ten interrupt sources with flags:
  - CTS changes
  - LIN break detection
  - Transmit data register empty
  - Transmission complete
  - Receive data register full
  - Idle line received
  - Overrun error
  - Framing error
  - Noise error
  - Parity error
- Multiprocessor communication - enter into mute mode if address match does not occur
- Wake up from mute mode (by idle line detection or address mark detection)
- Two receiver wakeup modes: Address bit (MSB, 9<sup>th</sup> bit), Idle line

### 23.3 USART functional description

The interface is externally connected to another device by three pins (see [Figure 179](#)). Any USART bidirectional communication requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

**RX:** Receive Data Input is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

**TX:** Transmit Data Output. When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire and smartcard modes, this I/O is used to transmit and receive the data (at USART level, data are then received on SW\_RX).

Through these pins, serial data is transmitted and received in normal USART mode as frames comprising:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (8 or 9 bits) least significant bit first
- 0.5, 1, 1.5, 2 Stop bits indicating that the frame is complete
- This interface uses a fractional baud rate generator - with a 12-bit mantissa and 4-bit fraction
- A status register (USART\_SR)
- Data Register (USART\_DR)
- A baud rate register (USART\_BRR) - 12-bit mantissa and 4-bit fraction.
- A Guardtime Register (USART\_GTPR) in case of Smartcard mode.

Refer to [Section 23.6: USART registers on page 551](#) for the definitions of each bit.

The following pin is required to interface in synchronous mode:

- **SCLK:** Transmitter clock output. This pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel data can be received synchronously on RX. This can be used to control peripherals that have shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable. In smartcard mode, SCLK can provide the clock to the smartcard.

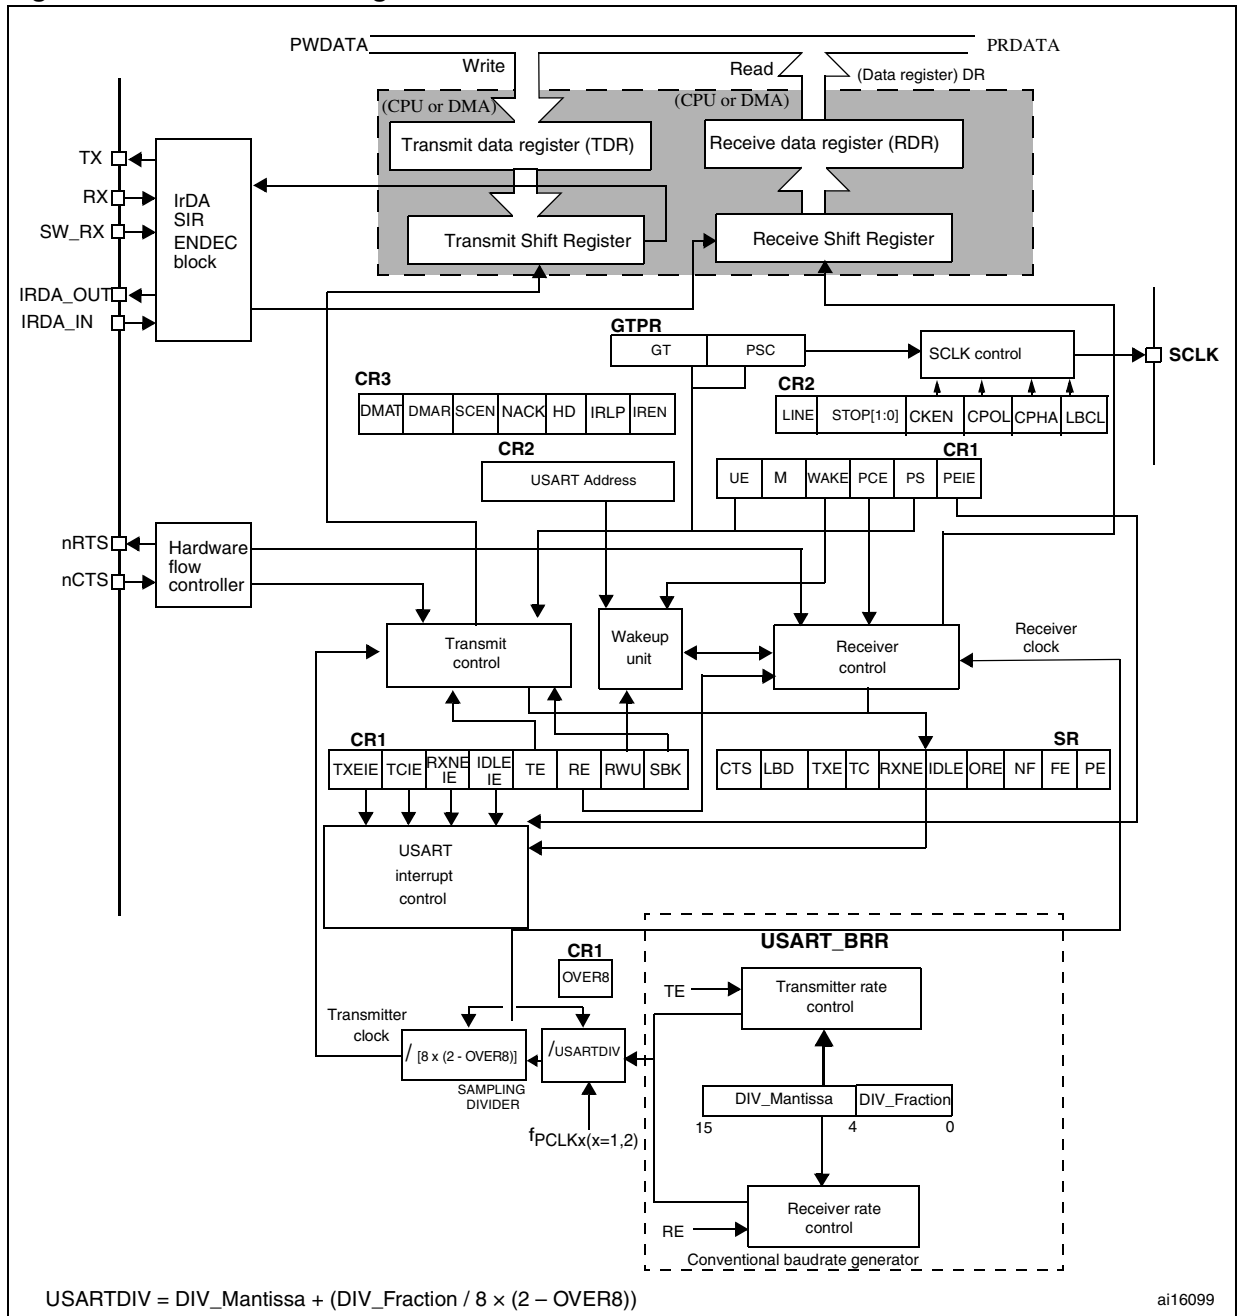

The following pins are required to interface in IrDA mode:

- **IrDA\_RDI:** Receive Data Input is the data input in IrDA mode.
- **IrDA\_TDO:** Transmit Data Output in IrDA mode.

the following pins are required in Hardware flow control mode:

- **nCTS:** Clear To Send blocks the data transmission at the end of the current transfer when high
- **nRTS:** Request to send indicates that the USART is ready to receive a data (when low).

Figure 179. USART block diagram

### 23.3.1 USART character description

Word length may be selected as being either 8 or 9 bits by programming the M bit in the USART\_CR1 register (see [Figure 180](#)).

The TX pin is in low state during the start bit. It is in high state during the stop bit.

An **Idle character** is interpreted as an entire frame of “1”s followed by the start bit of the next frame which contains data (The number of “1” ‘s will include the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame the transmitter inserts either 1 or 2 stop bits (logic “1” bit) to acknowledge the start bit.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.

**Figure 180. Word length programming**

### 23.3.2 Transmitter

The transmitter can send data words of either 8 or 9 bits depending on the M bit status. When the transmit enable bit (TE) is set, the data in the transmit shift register is output on the TX pin and the corresponding clock pulses are output on the SCLK pin.

#### Character transmission

During an USART transmission, data shifts out least significant bit first on the TX pin. In this mode, the USART\_DR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see [Figure 179](#)).

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by USART: 0.5, 1, 1.5 and 2 stop bits.

- Note:*
- 1 *The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission will corrupt the data on the TX pin as the baud rate counters will get frozen. The current data being transmitted will be lost.*
  - 2 *An idle frame will be sent after the TE bit is enabled.*

#### Configurable stop bits

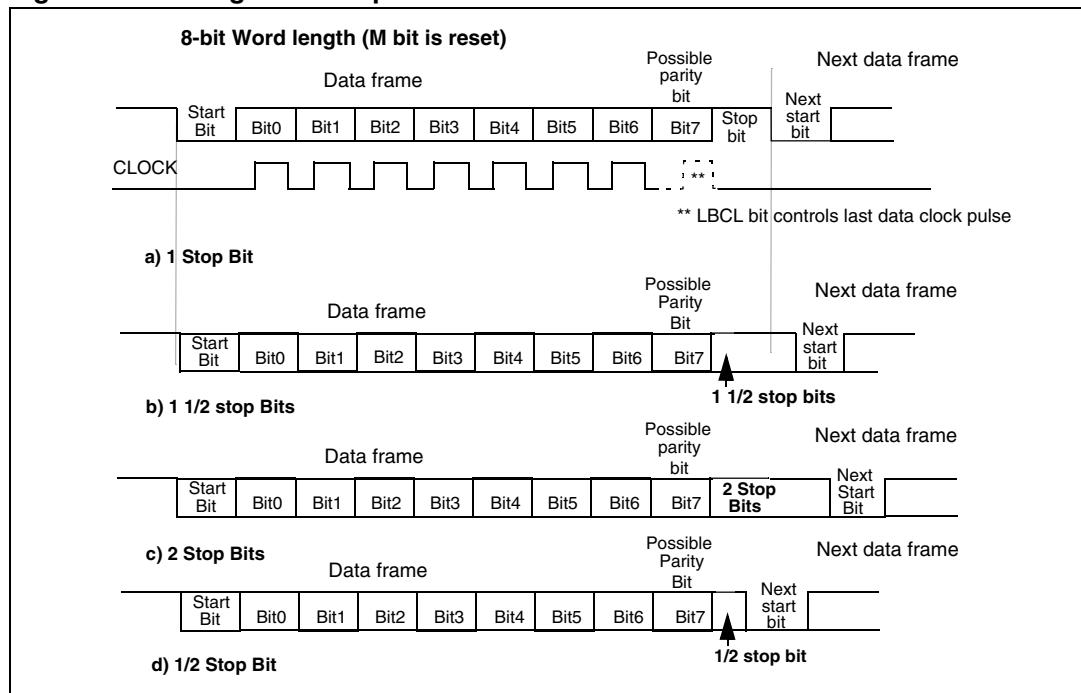

The number of stop bits to be transmitted with every character can be programmed in Control register 2, bits 13,12.

- 1 **1 stop bit:** This is the default value of number of stop bits.
- 2 **2 Stop bits:** This will be supported by normal USART, single-wire and modem modes.
- 3 **0.5 stop bit:** To be used when receiving data in Smartcard mode.
- 4 **1.5 stop bits:** To be used when transmitting and receiving data in Smartcard mode.

An idle frame transmission will include the stop bits.

A break transmission will be 10 low bits followed by the configured number of stop bits (when  $m = 0$ ) and 11 low bits followed by the configured number of stop bits (when  $m = 1$ ). It is not possible to transmit long breaks (break of length greater than 10/11 low bits).

Figure 181. Configurable stop bits

**Procedure:**

1. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
2. Program the M bit in USART\_CR1 to define the word length.
3. Program the number of stop bits in USART\_CR2.
4. Select DMA enable (DMAT) in USART\_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in multibuffer communication.
5. Select the desired baud rate using the USART\_BRR register.
6. Set the TE bit in USART\_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART\_DR register (this clears the TXE bit). Repeat this for each data to be transmitted in case of single buffer.
8. After writing the last data into the USART\_DR register, wait until TC=1. This indicates that the transmission of the last frame is complete. This is required for instance when the USART is disabled or enters the Halt mode to avoid corrupting the last transmission.

**Single byte communication**

Clearing the TXE bit is always performed by a write to the data register.

The TXE bit is set by hardware and it indicates:

- The data has been moved from TDR to the shift register and the data transmission has started.
- The TDR register is empty.
- The next data can be written in the USART\_DR register without overwriting the previous data.

This flag generates an interrupt if the TXEIE bit is set.

When a transmission is taking place, a write instruction to the USART\_DR register stores the data in the TDR register and which is copied in the shift register at the end of the current transmission.

When no transmission is taking place, a write instruction to the USART\_DR register places the data directly in the shift register, the data transmission starts, and the TXE bit is immediately set.

If a frame is transmitted (after the stop bit) and the TXE bit is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the USART\_CR1 register.

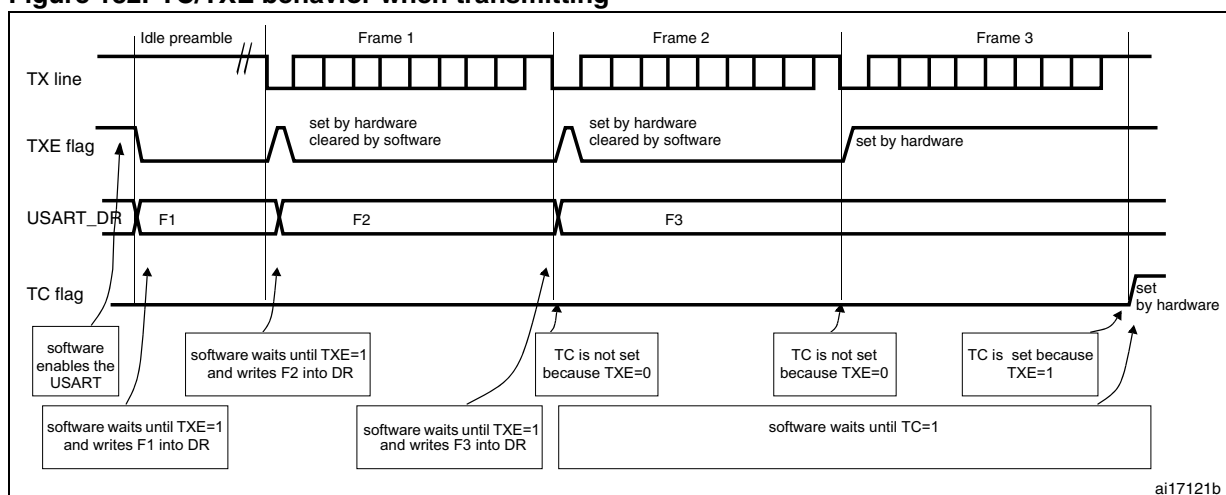

After writing the last data into the USART\_DR register, it is mandatory to wait for TC=1 before disabling the USART or causing the microcontroller to enter the low power mode (see [Figure 182: TC/TXE behavior when transmitting](#)).

The TC bit is cleared by the following software sequence:

1. A read from the USART\_SR register
2. A write to the USART\_DR register

*Note: The TC bit can also be cleared by writing a '0' to it. This clearing sequence is recommended only for Multibuffer communication.*

**Figure 182. TC/TXE behavior when transmitting**

**Break characters**

Setting the SBK bit transmits a break character. The break frame length depends on the M bit (see [Figure 180](#)).

If the SBK bit is set to '1' a break character is sent on the TX line after completing the current character transmission. This bit is reset by hardware when the break character is completed (during the stop bit of the break character). The USART inserts a logic 1 bit at the end of the last break frame to guarantee the recognition of the start bit of the next frame.

*Note: If the software resets the SBK bit before the commencement of break transmission, the break character will not be transmitted. For two consecutive breaks, the SBK bit should be set after the stop bit of the previous break.*

**Idle characters**

Setting the TE bit drives the USART to send an idle frame before the first data frame.

### 23.3.3 Receiver

The USART can receive data words of either 8 or 9 bits depending on the M bit in the USART\_CR1 register.

#### Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0 X 0 0 0 0.

Figure 183. Start bit detection when oversampling by 16 or 8

**Note:** If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set) where it waits for a falling edge.

The start bit is confirmed (RXNE flag set, interrupt generated if RXNEIE=1) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated (RXNE flag set, interrupt generated if RXNEIE=1) but the NE noise flag is set if, for both samplings, at least 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits). If this condition is not met, the start detection aborts and the receiver returns to the idle state (no flag is set).

If, for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0, the start bit is validated but the NE noise flag bit is set.

#### Character reception

During an USART reception, data shifts in least significant bit first through the RX pin. In this mode, the USART\_DR register consists of a buffer (RDR) between the internal bus and the received shift register.

Procedure:

1. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
2. Program the M bit in USART\_CR1 to define the word length.
3. Program the number of stop bits in USART\_CR2.
4. Select DMA enable (DMAR) in USART\_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication. STEP 3
5. Select the desired baud rate using the baud rate register USART\_BRR
6. Set the RE bit USART\_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- The RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- An interrupt is generated if the RXNEIE bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In multibuffer, RXNE is set after every byte received and is cleared by the DMA read to the Data Register.
- In single buffer mode, clearing the RXNE bit is performed by a software read to the USART\_DR register. The RXNE flag can also be cleared by writing a zero to it. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.

*Note: The RE bit should not be reset while receiving data. If the RE bit is disabled during reception, the reception of the current byte will be aborted.*

### Break character

When a break character is received, the USART handles it as a framing error.

### Idle character

When an idle frame is detected, there is the same procedure as a data received character plus an interrupt if the IDLEIE bit is set.

### Overrun error

An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared.

The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

- The ORE bit is set.
- The RDR content will not be lost. The previous data is available when a read to USART\_DR is performed.
- The shift register will be overwritten. After that point, any data received during overrun is lost.

- An interrupt is generated if either the RXNEIE bit is set or both the EIE and DMAR bits are set.
- The ORE bit is reset by a read to the USART\_SR register followed by a USART\_DR register read operation.

*Note:* The ORE bit, when set, indicates that at least 1 data has been lost. There are two possibilities:

- if  $RXNE=1$ , then the last valid data is stored in the receive register RDR and can be read,
- if  $RXNE=0$ , then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received. It may also occur when the new data is received during the reading sequence (between the USART\_SR register read access and the USART\_DR read access).

### Selecting the proper oversampling method

The receiver implements different user-configurable oversampling techniques (except in synchronous mode) for data recovery by discriminating between valid incoming data and noise.

The oversampling method can be selected by programming the OVER8 bit in the USART\_CR1 register and can be either 16 or 8 times the baud rate clock ([Figure 184](#) and [Figure 185](#)).

Depending on the application:

- select oversampling by 8 ( $OVER8=1$ ) to achieve higher speed (up to  $f_{PCLK}/8$ ). In this case the maximum receiver tolerance to clock deviation is reduced (refer to [Section 23.3.5: USART receiver's tolerance to clock deviation on page 533](#))
- select oversampling by 16 ( $OVER8=0$ ) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum  $f_{PCLK}/16$

Programming the ONEBIT bit in the USART\_CR3 register selects the method used to evaluate the logic level. There are two options:

- the majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NF bit is set
- a single sample in the center of the received bit

Depending on the application:

- select the three samples' majority vote method ( $ONEBITE=0$ ) when operating in a noisy environment and reject the data when a noise is detected (refer to [Figure 83](#)) because this indicates that a glitch occurred during the sampling.
- select the single sample method ( $ONEBITE=1$ ) when the line is noise-free to increase the receiver's tolerance to clock deviations (see [Section 23.3.5: USART receiver's tolerance to clock deviation on page 533](#)). In this case the NF bit will never be set.

When noise is detected in a frame:

- The NF bit is set at the rising edge of the RXNE bit.
- The invalid data is transferred from the Shift register to the USART\_DR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt will be issued if the EIE bit is set in the USART\_CR3 register.

The NF bit is reset by a USART\_SR register read operation followed by a USART\_DR register read operation.

*Note: Oversampling by 8 is not available in the Smartcard , IrDA and LIN modes. In those modes, the OVER8 bit is forced to '0 by hardware.*

**Figure 184. Data sampling when oversampling by 16**

**Figure 185. Data sampling when oversampling by 8**

**Table 83. Noise detection from sampled data**

Sampled value	NE status	Received bit value
000	0	0
001	1	0
010	1	0
011	1	1
100	1	0
101	1	1
110	1	1
111	0	1

**Framing error**

A framing error is detected when:

The stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- The FE bit is set by hardware
- The invalid data is transferred from the Shift register to the USART\_DR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt will be issued if the EIE bit is set in the USART\_CR3 register.

The FE bit is reset by a USART\_SR register read operation followed by a USART\_DR register read operation.

### Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of Control Register 2 - it can be either 1 or 2 in normal mode and 0.5 or 1.5 in Smartcard mode.

1. **0.5 stop bit (reception in Smartcard mode):** No sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
2. **1 stop bit:** Sampling for 1 stop Bit is done on the 8th, 9th and 10th samples.
3. **1.5 stop bits (Smartcard mode):** When transmitting in smartcard mode, the device must check that the data is correctly sent. Thus the receiver block must be enabled (RE =1 in the USART\_CR1 register) and the stop bit is checked to test if the smartcard has detected a parity error. In the event of a parity error, the smartcard forces the data signal low during the sampling - NACK signal-, which is flagged as a framing error. Then, the FE flag is set with the RXNE at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be decomposed into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through. Refer to [Section 23.3.11: Smartcard on page 542](#) for more details.
4. **2 stop bits:** Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. If a framing error is detected during the first stop bit the framing error flag will be set. The second stop bit is not checked for framing error. The RXNE flag will be set at the end of the first stop bit.

### 23.3.4 Fractional baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the Mantissa and Fraction values of USARTDIV.

#### Equation 1: Baud rate for standard USART (SPI mode included)

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{8 \times (2 - \text{OVER8}) \times \text{USARTDIV}}$$

#### Equation 2: Baud rate in Smartcard, LIN and IrDA modes

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{16 \times \text{USARTDIV}}$$

USARTDIV is an unsigned fixed point number that is coded on the USART\_BRR register.

- When OVER8=0, the fractional part is coded on 4 bits and programmed by the DIV\_fraction[3:0] bits in the USART\_BRR register
- When OVER8=1, the fractional part is coded on 3 bits and programmed by the DIV\_fraction[2:0] bits in the USART\_BRR register, and bit DIV\_fraction[3] must be kept cleared.

*Note:* The baud counters are updated to the new value in the baud registers after a write operation to USART\_BRR. Hence the baud rate register value should not be changed during communication.

### How to derive USARTDIV from USART\_BRR register values when OVER8=0

#### Example 1:

If DIV\_Mantissa = 0d27 and DIV\_Fraction = 0d12 (USART\_BRR = 0x1BC), then

Mantissa (USARTDIV) = 0d27

Fraction (USARTDIV) =  $12/16 = 0d0.75$

Therefore USARTDIV = 0d27.75

#### Example 2:

To program USARTDIV = 0d25.62

This leads to:

$DIV\_Fraction = 16 * 0d0.62 = 0d9.92$

The nearest real number is 0d10 = 0xA

$DIV\_Mantissa = \text{mantissa}(0d25.620) = 0d25 = 0x19$

Then, USART\_BRR = 0x19A hence USARTDIV = 0d25.625

#### Example 3:

To program USARTDIV = 0d50.99

This leads to:

$DIV\_Fraction = 16 * 0d0.99 = 0d15.84$

The nearest real number is 0d16 = 0x10 => overflow of DIV\_frac[3:0] => carry must be added up to the mantissa

$DIV\_Mantissa = \text{mantissa}(0d50.990 + \text{carry}) = 0d51 = 0x33$

Then, USART\_BRR = 0x330 hence USARTDIV = 0d51.000

### How to derive USARTDIV from USART\_BRR register values when OVER8=1

#### Example 1:

If DIV\_Mantissa = 0x27 and DIV\_Fraction[2:0]= 0d6 (USART\_BRR = 0x1B6), then

Mantissa (USARTDIV) = 0d27

Fraction (USARTDIV) =  $6/8 = 0d0.75$

Therefore USARTDIV = 0d27.75

**Example 2:**

To program USARTDIV = 0d25.62

This leads to:

$$\text{DIV\_Fraction} = 8 * 0d0.62 = 0d4.96$$

The nearest real number is 0d5 = 0x5

$$\text{DIV\_Mantissa} = \text{mantissa} (0d25.620) = 0d25 = 0x19$$

Then, USART\_BRR = 0x195 => USARTDIV = 0d25.625

**Example 3:**

To program USARTDIV = 0d50.99

This leads to:

$$\text{DIV\_Fraction} = 8 * 0d0.99 = 0d7.92$$

The nearest real number is 0d8 = 0x8 => overflow of the DIV\_frac[2:0] => carry must be added up to the mantissa

$$\text{DIV\_Mantissa} = \text{mantissa} (0d50.990 + \text{carry}) = 0d51 = 0x33$$

Then, USART\_BRR = 0x0330 => USARTDIV = 0d51.000

**Table 84. Error calculation for programmed baud rates at f<sub>PCLK</sub> = 8 MHz or f<sub>PCLK</sub> = 12 MHz), oversampling by 16<sup>(1)</sup>**

### 23.3.5 USART receiver's tolerance to clock deviation

The USART's asynchronous receiver works correctly only if the total clock system deviation is smaller than the USART receiver's tolerance. The causes which contribute to the total deviation are:

- DTRA: Deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- DQUANT: Error due to the baud rate quantization of the receiver
- DREC: Deviation of the receiver's local oscillator
- DTCL: Deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

$$DTRA + DQUANT + DREC + DTCL < \text{USART receiver's tolerance}$$

The USART receiver’s tolerance to properly receive data is equal to the maximum tolerated deviation and depends on the following choices:

- 10- or 11-bit character length defined by the M bit in the USART\_CR1 register
- oversampling by 8 or 16 defined by the OVER8 bit in the USART\_CR1 register
- use of fractional baud rate or not
- use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBITE bit in the USART\_CR3 register

**Table 92. USART receiver’s tolerance when DIV fraction is 0**

M bit	OVER8 bit = 0		OVER8 bit = 1	
	ONEBITE=0	ONEBITE=1	ONEBITE=0	ONEBITE=1
0	3.75%	4.375%	2.50%	3.75%
1	3.41%	3.97%	2.27%	3.41%

**Table 93. USART receiver’s tolerance when DIV\_Fraction is different from 0**

M bit	OVER8 bit = 0		OVER8 bit = 1	
	ONEBITE=0	ONEBITE=1	ONEBITE=0	ONEBITE=1
0	3.33%	3.88%	2%	3%
1	3.03%	3.53%	1.82%	2.73%

*Note:* The figures specified in [Table 92](#) and [Table 93](#) may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M=0 (11-bit times when M=1).

### 23.3.6 Multiprocessor communication

There is a possibility of performing multiprocessor communication with the USART (several USARTs connected in a network). For instance one of the USARTs can be the master, its TX output is connected to the RX input of the other USART. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In mute mode:

- None of the reception status bits can be set.
- All the receive interrupts are inhibited.
- The RWU bit in USART\_CR1 register is set to 1. RWU can be controlled automatically by hardware or written by the software under certain conditions.

The USART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the USART\_CR1 register:

- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

### Idle line detection (WAKE=0)

The USART enters mute mode when the RWU bit is written to 1.

It wakes up when an Idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the USART\_SR register. RWU can also be written to 0 by software.

An example of mute mode behavior using Idle line detection is given in [Figure 186](#).

**Figure 186. Mute mode using Idle line detection**

### Address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a '1' else they are considered as data. In an address byte, the address of the targeted receiver is put on the 4 LSB. This 4-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART\_CR2 register.

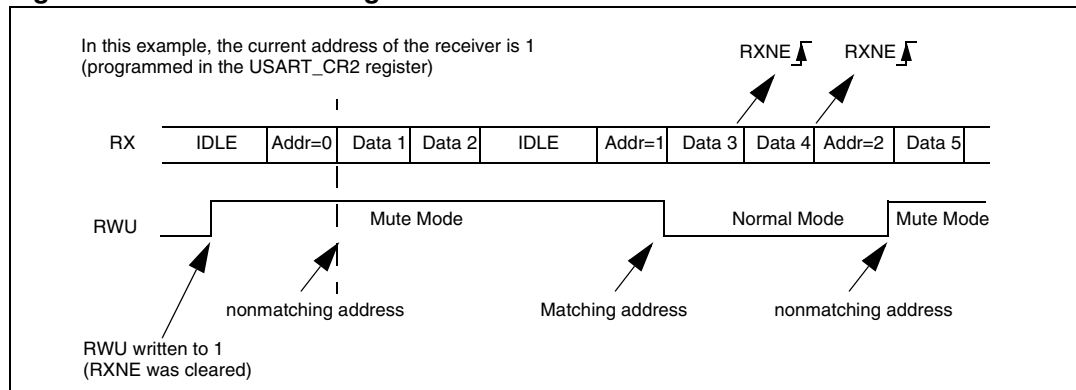

The USART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt nor DMA request is issued as the USART would have entered mute mode.

It exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE bit is set for the address character since the RWU bit has been cleared.

The RWU bit can be written to as 0 or 1 when the receiver buffer contains no data (RXNE=0 in the USART\_SR register). Otherwise the write attempt is ignored.

An example of mute mode behavior using address mark detection is given in [Figure 187](#).

**Figure 187. Mute mode using address mark detection**

### 23.3.7 Parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART\_CR1 register. Depending on the frame length defined by the M bit, the possible USART frame formats are as listed in [Table 94](#).

**Table 94. Frame formats**

M bit	PCE bit	USART frame <sup>(1)</sup>
0	0	SB   8 bit data   STB
0	1	SB   7-bit data   PB   STB
1	0	SB   9-bit data   STB
1	1	SB   8-bit data PB   STB

1. Legends: SB: start bit, STB: stop bit, PB: parity bit.

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

E.g.: data=00110101; 4 bits set => parity bit will be 0 if even parity is selected (PS bit in USART\_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

E.g.: data=00110101; 4 bits set => parity bit will be 1 if odd parity is selected (PS bit in USART\_CR1 = 1).

#### Parity checking in reception

If the parity check fails, the PE flag is set in the USART\_SR register and an interrupt is generated if PEIE is set in the USART\_CR1 register. The PE flag is cleared by a software sequence (a read from the status register followed by a read or write access to the USART\_DR data register).

*Note:* In case of wakeup by an address mark: the MSB bit of the data is taken into account to identify an address but not the parity bit. And the receiver does not check the parity of the address data (PE is not set in case of a parity error).

#### Parity generation in transmission

If the PCE bit is set in USART\_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

*Note:* The software routine that manages the transmission can activate the software sequence which clears the PE flag (a read from the status register followed by a read or write access to the data register). When operating in half-duplex mode, depending on the software, this can cause the PE flag to be unexpectedly cleared.

### 23.3.8 LIN (local interconnection network) mode

The LIN mode is selected by setting the LINEN bit in the USART\_CR2 register. In LIN mode, the following bits must be kept cleared:

- CLKEN in the USART\_CR2 register,
- STOP[1:0], SCEN, HDSEL and IREN in the USART\_CR3 register.

#### LIN transmission

The same procedure explained in [Section 23.3.2](#) has to be applied for LIN Master transmission than for normal USART transmission with the following differences:

- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBK bit sends 13 '0 bits as a break character. Then a bit of value '1 is sent to allow the next start detection.

#### LIN reception

A break detection circuit is implemented on the USART interface. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART\_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART\_CR2) or 11 (when LBDL=1 in USART\_CR2) consecutive bits are detected as '0, and are followed by a delimiter character, the LBD flag is set in USART\_SR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a '1 is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

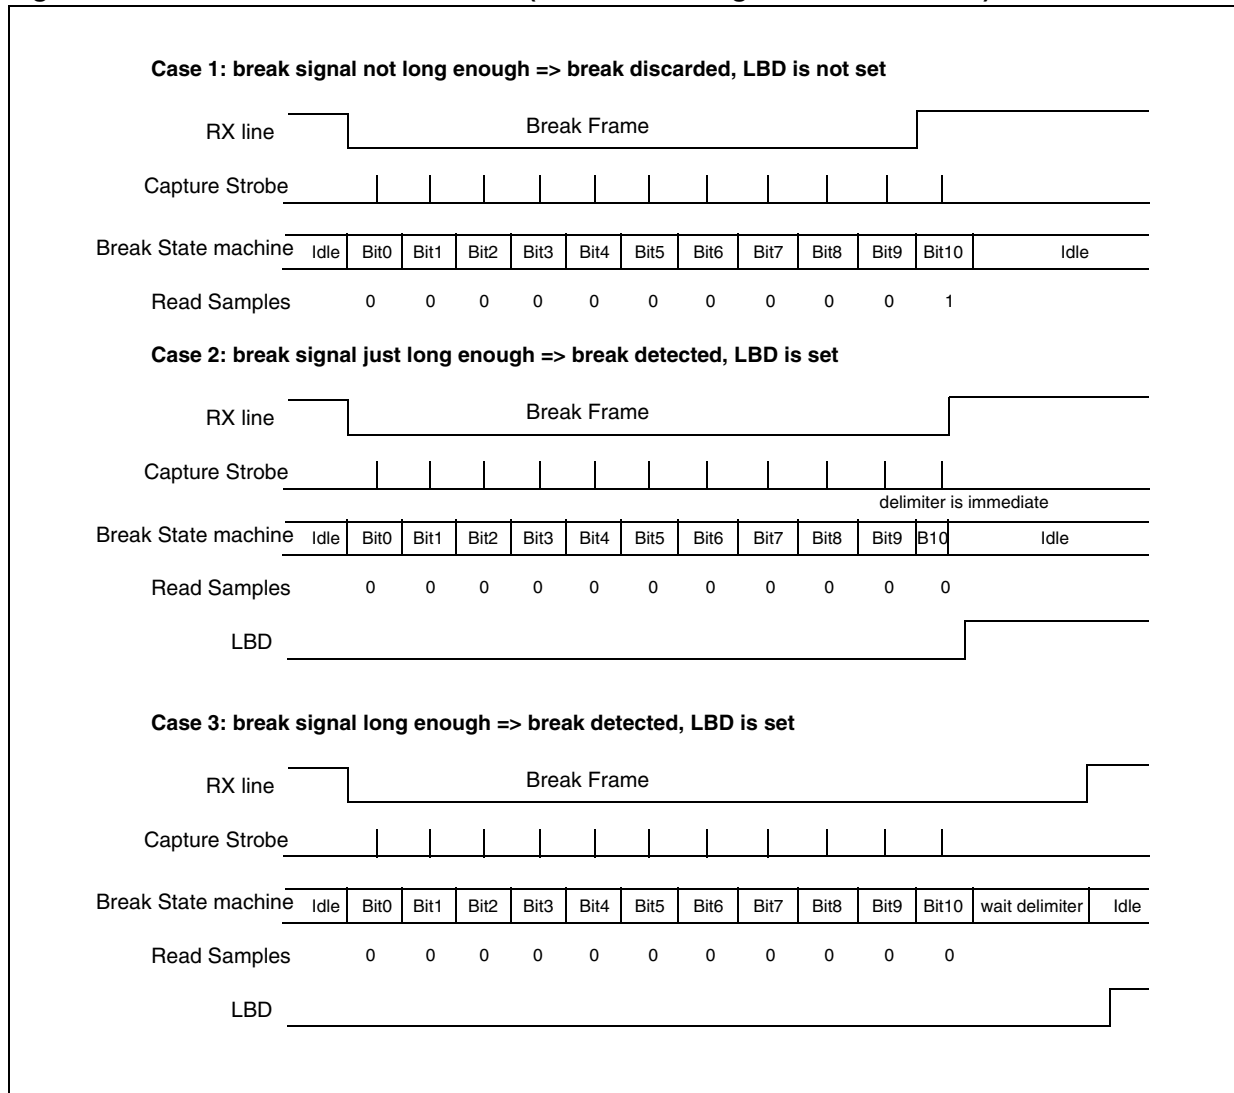

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at '0, which will be the case for any break frame), the receiver stops until the break detection circuit receives either a '1, if the break word was not complete, or a delimiter character if a break has been detected.

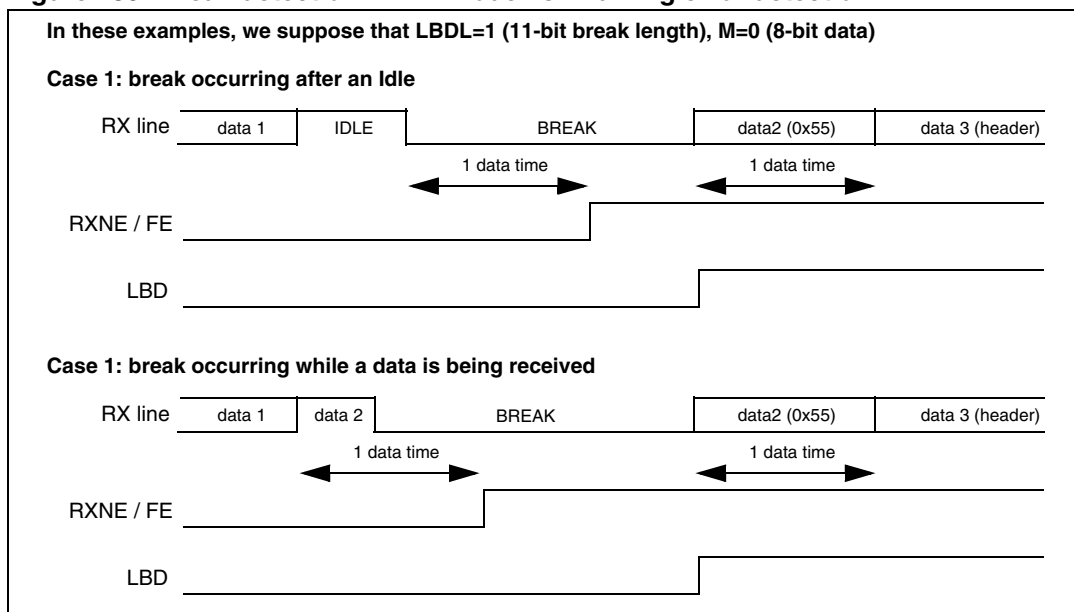

The behavior of the break detector state machine and the break flag is shown on the [Figure 188: Break detection in LIN mode \(11-bit break length - LBDL bit is set\) on page 538](#).

Examples of break frames are given on [Figure 189: Break detection in LIN mode vs. Framing error detection on page 539](#).

Figure 188. Break detection in LIN mode (11-bit break length - LBDL bit is set)

**Figure 189. Break detection in LIN mode vs. Framing error detection**

### 23.3.9 USART synchronous mode

The synchronous mode is selected by writing the CLKEN bit in the USART\_CR2 register to 1. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- SCEN, HDSEL and IREN bits in the USART\_CR3 register.

The USART allows the user to control a bidirectional synchronous serial communications in master mode. The SCLK pin is the output of the USART transmitter clock. No clock pulses are sent to the SCLK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART\_CR2 register clock pulses will or will not be generated during the last valid data bit (address mark). The CPOL bit in the USART\_CR2 register allows the user to select the clock polarity, and the CPHA bit in the USART\_CR2 register allows the user to select the phase of the external clock (see [Figure 190](#), [Figure 191](#) & [Figure 192](#)).

During the Idle state, preamble and send break, the external SCLK clock is not activated.

In synchronous mode the USART transmitter works exactly like in asynchronous mode. But as SCLK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In this mode the USART receiver works in a different manner compared to the asynchronous mode. If RE=1, the data is sampled on SCLK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).

- Note:*
- 1 The SCLK pin works in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and a data is being transmitted (the data register USART\_DR has been written). This means that it is not possible to receive a synchronous data without transmitting data.
  - 2 The LBCL, CPOL and CPHA bits have to be selected when both the transmitter and the receiver are disabled (TE=RE=0) to ensure that the clock pulses function correctly. These bits should not be changed while the transmitter or the receiver is enabled.

- 3 It is advised that TE and RE are set in the same instruction in order to minimize the setup and the hold time of the receiver.
- 4 The USART supports master mode only: it cannot receive or send data related to an input clock (SCLK is always an output).

Figure 190. USART example of synchronous transmission

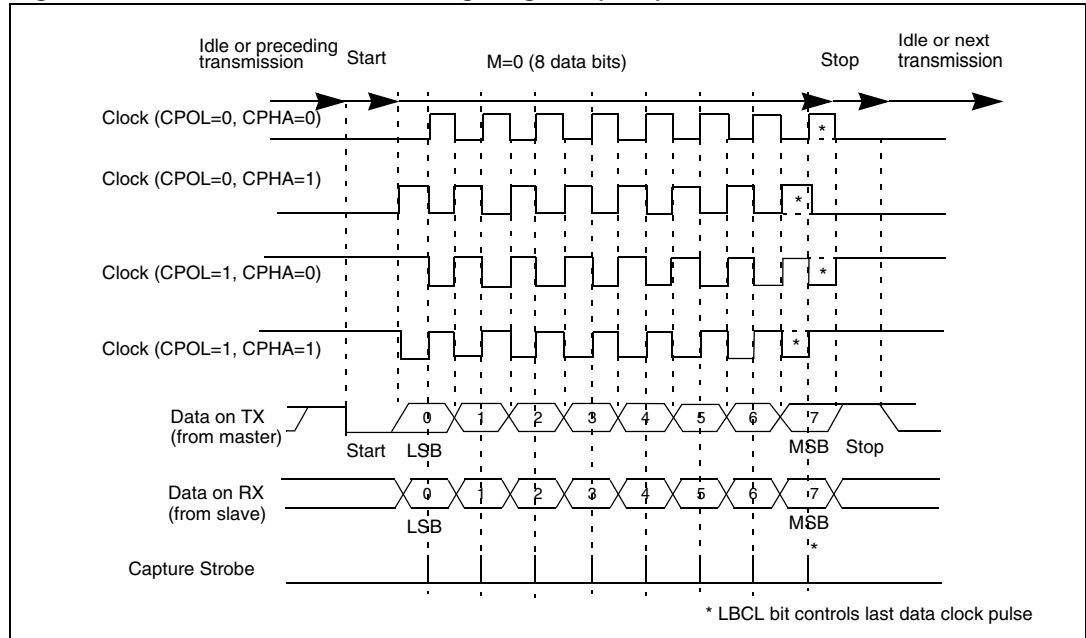

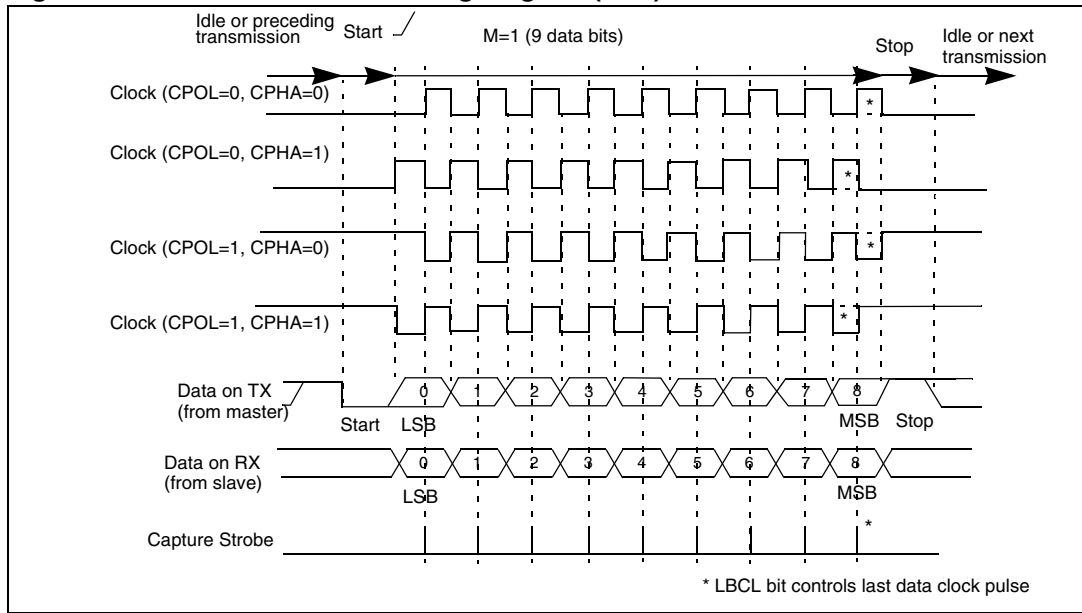

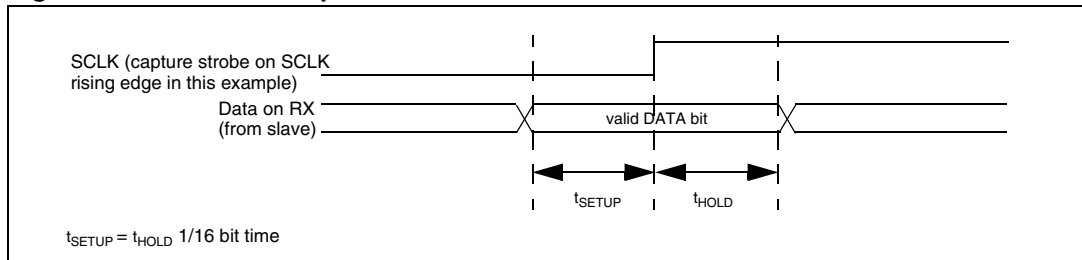

Figure 191. USART data clock timing diagram (M=0)

**Figure 192. USART data clock timing diagram (M=1)**

**Figure 193. RX data setup/hold time**

*Note:* The function of SCLK is different in Smartcard mode. Refer to the Smartcard mode chapter for more details.

### 23.3.10 Single-wire half-duplex communication

The single-wire half-duplex mode is selected by setting the HDSEL bit in the USART\_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART\_CR2 register,
- SCEN and IREN bits in the USART\_CR3 register.

The USART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and full-duplex communication is made with a control bit 'HALF DUPLEX SEL' (HDSEL in USART\_CR3).

As soon as HDSEL is written to 1:

- the TX and RX lines are internally connected
- the RX pin is no longer used
- the TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as floating input (or output high open-drain) when not driven by the USART.

Apart from this, the communications are similar to what is done in normal USART mode. The conflicts on the line must be managed by the software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continue to occur as soon as a data is written in the data register while the TE bit is set.

### 23.3.11 Smartcard

The Smartcard mode is selected by setting the SCEN bit in the USART\_CR3 register. In smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- HDSEL and IREN bits in the USART\_CR3 register.

Moreover, the CLKEN bit may be set in order to provide a clock to the smartcard.

The Smartcard interface is designed to support asynchronous protocol Smartcards as defined in the ISO 7816-3 standard. The USART should be configured as:

- 8 bits plus parity: where M=1 and PCE=1 in the USART\_CR1 register
- 1.5 stop bits when transmitting and receiving : where STOP=11 in the USART\_CR2 register.

*Note:* It is also possible to choose 0.5 stop bit for receiving but it is recommended to use 1.5 stop bits for both transmitting and receiving to avoid switching between the two configurations.

Figure 194 shows examples of what can be seen on the data line with and without parity error.

**Figure 194. ISO 7816-3 asynchronous protocol**

When connected to a smartcard, the TX output of the USART drives a bidirectional line that the smartcard also drives into. To do so, SW\_RX must be connected on the same I/O than TX at product level. The Transmitter output enable TX\_EN is asserted during the transmission of the start bit and the data byte, and is deasserted during the stop bit (weak pull up), so that the receive can drive the line in case of a parity error. If TX\_EN is not used, TX is driven at high level during the stop bit: Thus the receiver can drive the line as long as TX is configured in open-drain.

Smartcard is a single wire half duplex communication protocol.

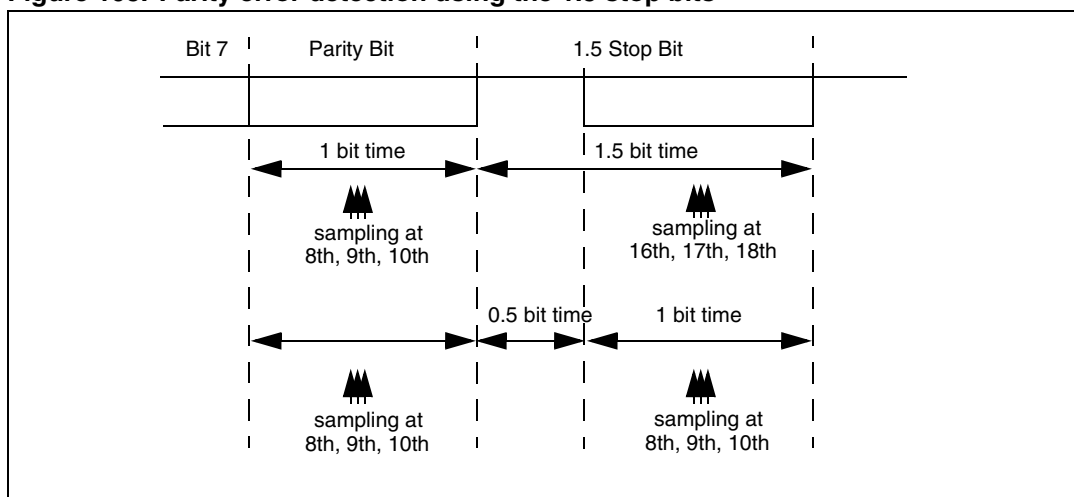

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register will start shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.

- If a parity error is detected during reception of a frame programmed with a 0.5 or 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the Smartcard that the data transmitted to USART has not been correctly received. This NACK signal (pulling transmit line low for 1 baud clock) will cause a framing error on the transmitter side (configured with 1.5 stop bits). The application can handle re-sending of data according to the protocol. A parity error is 'NACK'ed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted.
- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the guard time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the guard time counter reaches the programmed value TC is asserted high.
- The de-assertion of TC flag is unaffected by Smartcard mode.
- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK will not be detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.
- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver will not detect the NACK as a start bit.

- Note: 1 A break character is not significant in Smartcard mode. A 0x00 data with a framing error will be treated as data and not as a break.
- 2 No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 195 details how the NACK signal is sampled by the USART. In this example the USART is transmitting a data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.

Figure 195. Parity error detection using the 1.5 stop bits

The USART can provide a clock to the smartcard through the SCLK output. In smartcard mode, SCLK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the

prescaler register USART\_GTPR. SCLK frequency can be programmed from  $f_{CK}/2$  to  $f_{CK}/62$ , where  $f_{CK}$  is the peripheral input clock.

### 23.3.12 IrDA SIR ENDEC block

The IrDA mode is selected by setting the IREN bit in the USART\_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART\_CR2 register,
- SCEN and HDSEL bits in the USART\_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see [Figure 196](#)).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2Kbps for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to USART. The decoder input is normally HIGH (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (i.e. the USART is sending data to the IrDA encoder), any data on the IrDA receive line will be ignored by the IrDA decoder and if the Receiver is busy (USART is receiving decoded data from the USART), data on the TX from the USART to IrDA will not be encoded by IrDA. While receiving data, transmission should be avoided as the data to be transmitted could be corrupted.
- A '0 is transmitted as a high pulse and a '1 is transmitted as a '0. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see [Figure 197](#)).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41 us. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the IrDA low-power Baud Register, USART\_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods will be accepted as a pulse. The IrDA encoder/decoder doesn't work when PSC=0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the STOP bits in the USART\_CR2 register must be configured to "1 stop bit".

**IrDA low-power mode**

**Transmitter:**

In low-power mode the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally this value is 1.8432 MHz (1.42 MHz < PSC < 2.12 MHz). A low-power mode programmable divisor divides the system clock to achieve this value.

**Receiver:**

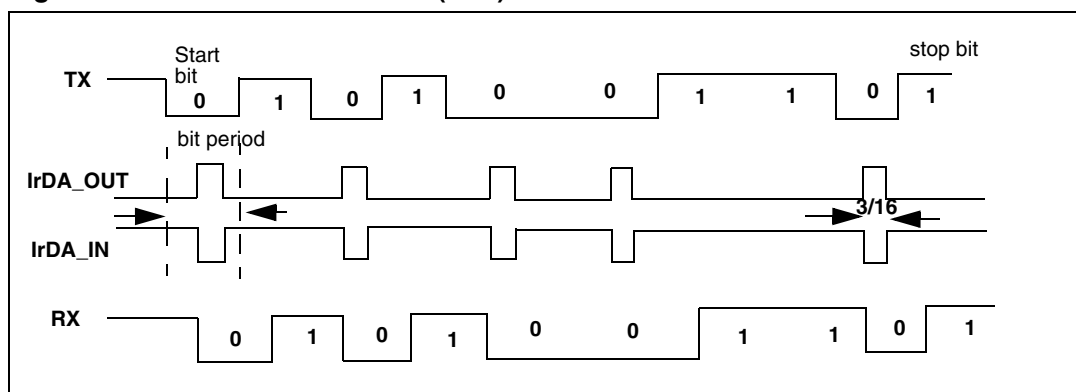

Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1/PSC. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in USART\_GTPR).

- Note:*
- 1 A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.
  - 2 The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).

**Figure 196. IrDA SIR ENDEC- block diagram**

**Figure 197. IrDA data modulation (3/16) -Normal mode**

### 23.3.13 Continuous communication using DMA

The USART is capable of continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

*Note:* You should refer to product specs for availability of the DMA controller. If DMA is not available in the product, you should use the USART as explained in [Section 23.3.2](#) or [23.3.3](#). In the USART\_SR register, you can clear the TXE/ RXNE flags to achieve continuous communication.

#### Transmission using DMA

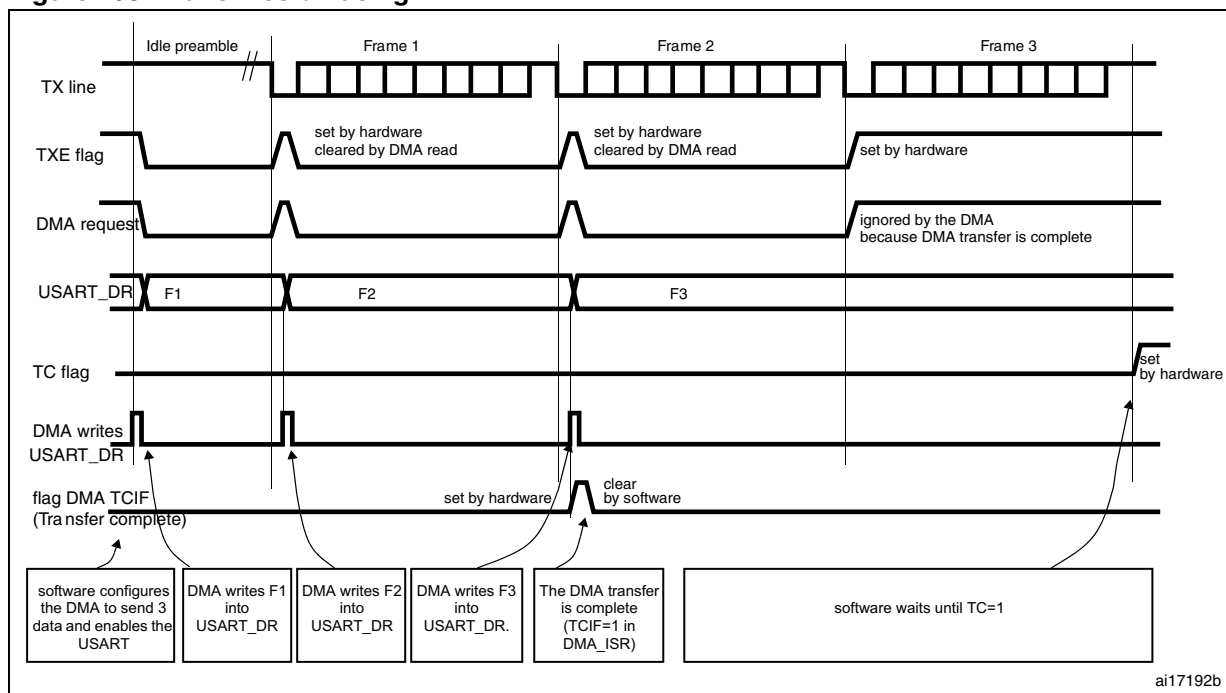

DMA mode can be enabled for transmission by setting DMAT bit in the USART\_CR3 register. Data is loaded from a SRAM area configured using the DMA peripheral (refer to the DMA specification) to the USART\_DR register whenever the TXE bit is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART\_DR register address in the DMA control register to configure it as the destination of the transfer. The data will be moved to this address from memory after each TXE event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data will be loaded into the USART\_DR register from this memory area after each TXE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC bit in the SR register by writing 0 to it.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA\_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or entering the Stop mode. The software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the last frame's end of transmission.

Figure 198. Transmission using DMA

### Reception using DMA

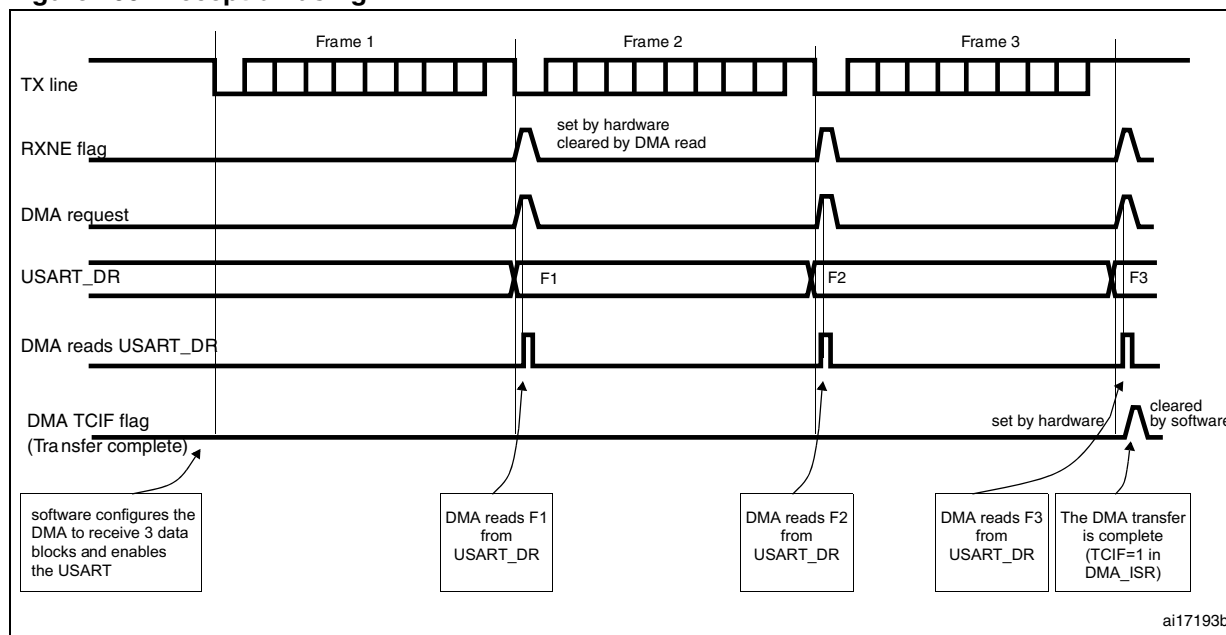

DMA mode can be enabled for reception by setting the DMAR bit in USART\_CR3 register. Data is loaded from the USART\_DR register to a SRAM area configured using the DMA peripheral (refer to the DMA specification) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART\_DR register address in the DMA control register to configure it as the source of the transfer. The data will be moved from this address to the memory after each RXNE event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data will be loaded from USART\_DR to this memory area after each RXNE event.
3. Configure the total number of bytes to be transferred in the DMA control register.
4. Configure the channel priority in the DMA control register
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector. The DMAR bit should be cleared by software in the USART\_CR3 register during the interrupt subroutine.

*Note:* If DMA is used for reception, do not enable the RXNEIE bit.

Figure 199. Reception using DMA

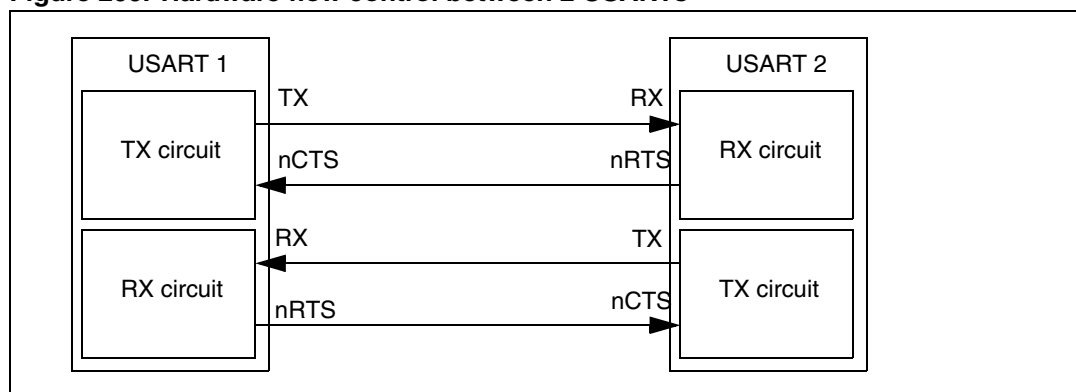

### Error flagging and interrupt generation in multibuffer communication

In case of multibuffer communication if any error occurs during the transaction the error flag will be asserted after the current byte. An interrupt will be generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE in case of single byte reception, there will be separate error flag interrupt enable bit (EIE bit in the USART\_CR3 register), which if set will issue an interrupt after the current byte with either of these errors.

### 23.3.14 Hardware flow control

It is possible to control the serial data flow between 2 devices by using the nCTS input and the nRTS output. The [Figure 200](#) shows how to connect 2 devices in this mode:

Figure 200. Hardware flow control between 2 USARTs

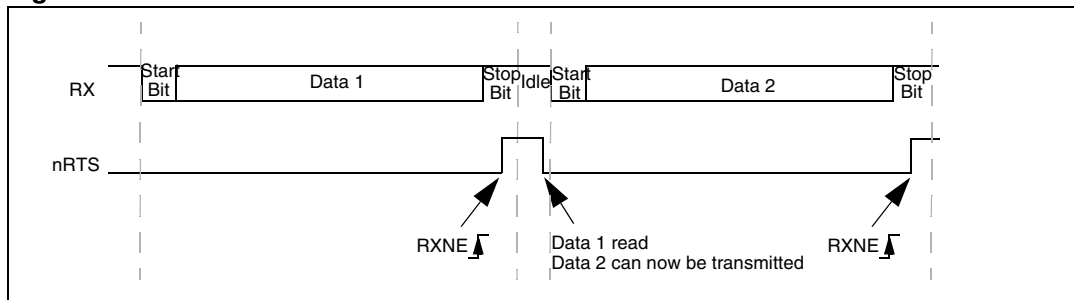

RTS and CTS flow control can be enabled independently by writing respectively RTSE and CTSE bits to 1 (in the USART\_CR3 register).

### RTS flow control

If the RTS flow control is enabled (RTSE=1), then nRTS is asserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, nRTS is deasserted, indicating that the transmission is expected to stop at the end of the current frame. *Figure 201* shows an example of communication with RTS flow control enabled.

**Figure 201. RTS flow control**

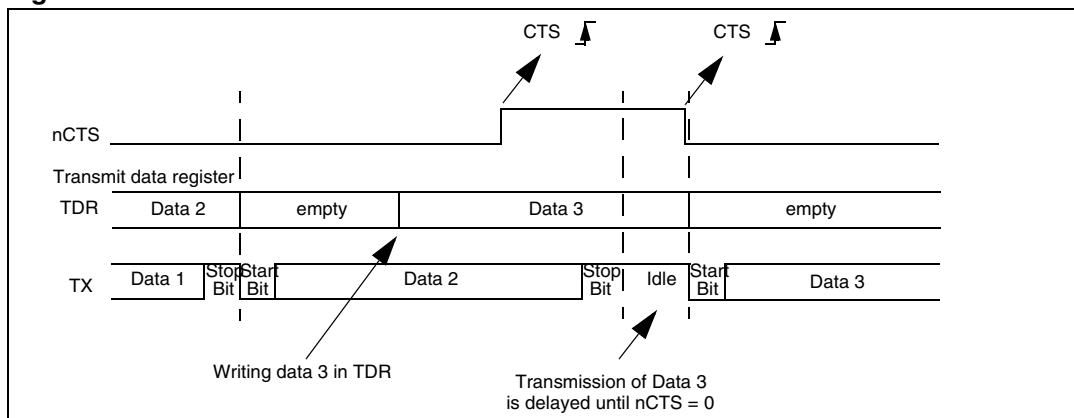

### CTS flow control

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the nCTS input before transmitting the next frame. If nCTS is asserted (tied low), then the next data is transmitted (assuming that a data is to be transmitted, in other words, if TXE=0), else the transmission does not occur. When nCTS is deasserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the nCTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART\_CR3 register is set. The figure below shows an example of communication with CTS flow control enabled.

**Figure 202. CTS flow control**

*Note:* **Special behavior of break frames:** when the CTS flow is enabled, the transmitter does not check the nCTS input state to send a break.

## 23.4 USART interrupts

**Table 95. USART interrupt requests**

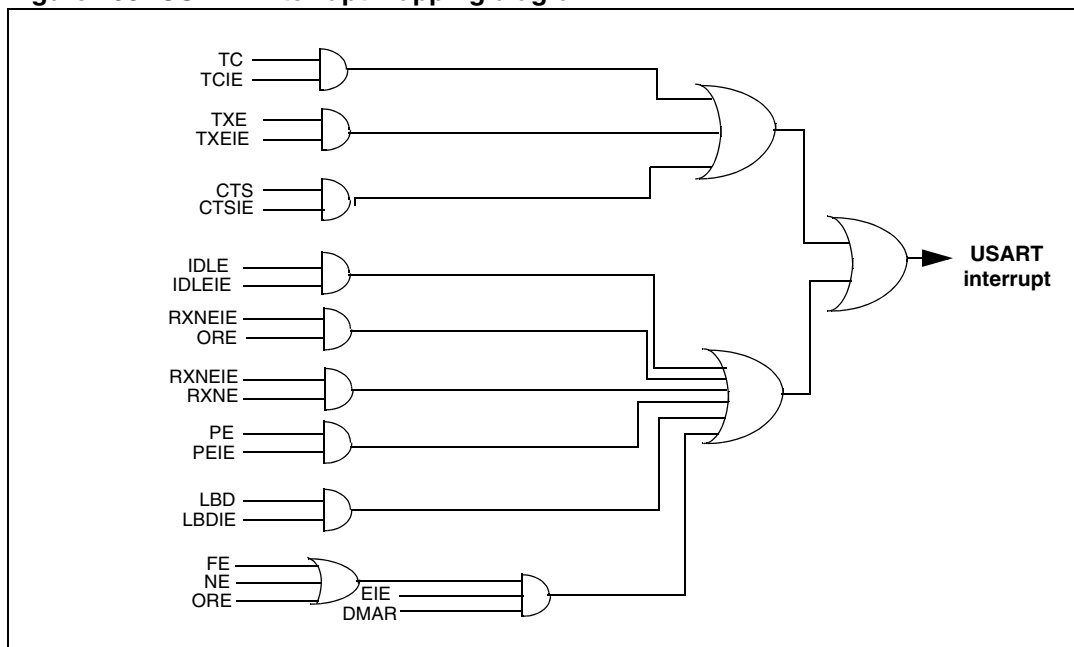

Interrupt event	Event flag	Enable control bit
Transmit Data Register Empty	TXE	TXEIE
CTS flag	CTS	CTSIE
Transmission Complete	TC	TCIE
Received Data Ready to be Read	RXNE	RXNEIE
Overrun Error Detected	ORE	
Idle Line Detected	IDLE	IDLEIE
Parity Error	PE	PEIE
Break Flag	LBD	LBDIE
Noise Flag, Overrun error and Framing Error in multibuffer communication	NF or ORE or FE	EIE

The USART interrupt events are connected to the same interrupt vector (see [Figure 203](#)).

- During transmission: Transmission Complete, Clear to Send or Transmit Data Register empty interrupt.
- While receiving: Idle Line detection, Overrun error, Receive Data register not empty, Parity error, LIN break detection, Noise Flag (only in multi buffer communication) and Framing Error (only in multi buffer communication).

These events generate an interrupt if the corresponding Enable Control Bit is set.

**Figure 203. USART interrupt mapping diagram**

## 23.5 USART mode configuration

## 23.6 USART registers

Refer to [Section 1.1 on page 29](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

### 23.6.1 Status register (USART\_SR)

Address offset: 0x00

Reset value: 0x00C0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CTS	LBD	TXE	TC	RXNE	IDLE	ORE	NF	FE	PE
						rc_w0	rc_w0	r	rc_w0	rc_w0	r	r	r	r	r

Bits 31:10 Reserved, forced by hardware to 0.

Bit 9 **CTS**: CTS flag

This bit is set by hardware when the nCTS input toggles, if the CTSE bit is set. It is cleared by software (by writing it to 0). An interrupt is generated if CTSIE=1 in the USART\_CR3 register.

0: No change occurred on the nCTS status line

1: A change occurred on the nCTS status line

Bit 8 **LBD**: LIN break detection flag

This bit is set by hardware when the LIN break is detected. It is cleared by software (by writing it to 0). An interrupt is generated if LBDIE = 1 in the USART\_CR2 register.

0: LIN Break not detected

1: LIN break detected

*Note: An interrupt is generated when LBD=1 if LBDIE=1*

Bit 7 **TXE**: Transmit data register empty

This bit is set by hardware when the content of the TDR register has been transferred into the shift register. An interrupt is generated if the TXEIE bit =1 in the USART\_CR1 register. It is cleared by a write to the USART\_DR register.

0: Data is not transferred to the shift register

1: Data is transferred to the shift register)

*Note: This bit is used during single buffer transmission.*

Bit 6 **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE=1 in the USART\_CR1 register. It is cleared by a software sequence (a read from the USART\_SR register followed by a write to the USART\_DR register). The TC bit can also be cleared by writing a '0' to it. This clearing sequence is recommended only for multibuffer communication.

0: Transmission is not complete

1: Transmission is complete

**Bit 5 RXNE:** Read data register not empty

This bit is set by hardware when the content of the RDR shift register has been transferred to the USART\_DR register. An interrupt is generated if RXNEIE=1 in the USART\_CR1 register. It is cleared by a read to the USART\_DR register. The RXNE flag can also be cleared by writing a zero to it. This clearing sequence is recommended only for multibuffer communication.

0: Data is not received

1: Received data is ready to be read.

**Bit 4 IDLE:** IDLE line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if the IDLEIE=1 in the USART\_CR1 register. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No Idle Line is detected

1: Idle Line is detected

*Note: The IDLE bit will not be set again until the RXNE bit has been set itself (i.e. a new idle line occurs).*

**Bit 3 ORE:** Overrun error

This bit is set by hardware when the word currently being received in the shift register is ready to be transferred into the RDR register while RXNE=1. An interrupt is generated if RXNEIE=1 in the USART\_CR1 register. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No Overrun error

1: Overrun error is detected

*Note: When this bit is set, the RDR register content will not be lost but the shift register will be overwritten. An interrupt is generated on ORE flag in case of Multi Buffer communication if the EIE bit is set.*

**Bit 2 NF:** Noise detected flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No noise is detected

1: Noise is detected

*Note: This bit does not generate interrupt as it appears at the same time as the RXNE bit which itself generates an interrupting interrupt is generated on NF flag in case of Multi Buffer communication if the EIE bit is set.*

*Note: When the line is noise-free, the NF flag can be disabled by programming the ONEBITE bit to 1 to increase the USART tolerance to deviations (Refer to [Section 23.3.5: USART receiver's tolerance to clock deviation on page 533](#)).*

**Bit 1 FE:** Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No Framing error is detected

1: Framing error or break character is detected

*Note: This bit does not generate interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. If the word currently being transferred causes both frame error and overrun error, it will be transferred and only the ORE bit will be set. An interrupt is generated on FE flag in case of Multi Buffer communication if the EIE bit is set.*

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by a software sequence (a read from the status register followed by a read or write access to the USART\_DR data register). The software must wait for the RXNE flag to be set before clearing the PE bit.

An interrupt is generated if PEIE = 1 in the USART\_CR1 register.

0: No parity error

1: Parity error

### 23.6.2 Data register (USART\_DR)

Address offset: 0x04

Reset value: Undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Reserved																
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved							DR[8:0]									
							rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, forced by hardware to 0.

Bits 8:0 **DR[8:0]**: Data value

Contains the Received or Transmitted data character, depending on whether it is read from or written to.

The Data register performs a double function (read and write) since it is composed of two registers, one for transmission (TDR) and one for reception (RDR)

The TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 1).

The RDR register provides the parallel interface between the input shift register and the internal bus.

When transmitting with the parity enabled (PCE bit set to 1 in the USART\_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

### 23.6.3 Baud rate register (USART\_BRR)

*Note: The baud counters stop counting if the TE or RE bits are disabled respectively.*

Address offset: 0x08

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIV_Mantissa[11:0]											DIV_Fraction[3:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, forced by hardware to 0.

Bits 15:4 **DIV\_Mantissa[11:0]**: mantissa of USARTDIV

These 12 bits define the mantissa of the USART Divider (USARTDIV)

Bits 3:0 **DIV\_Fraction[3:0]**: fraction of USARTDIV

These 4 bits define the fraction of the USART Divider (USARTDIV). When OVER8=1, the DIV\_Fraction3 bit is not considered and must be kept cleared.

### 23.6.4 Control register 1 (USART\_CR1)

Address offset: 0x0C

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OVER8	Reserved	UE	M	WAKE	PCE	PS	PEIE	TXEIE	TCIE	RXNEIE	IDLEIE	TE	RE	RWU	SBK
rw	Res.	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, forced by hardware to 0.

Bit 15 **OVER8** : Oversampling mode

0: oversampling by 16

1: oversampling by 8

*Note: Oversampling by 8 is not available in the Smartcard, IrDA and LIN modes: when SCEN=1, IREN=1 or LINEN=1 then OVER8 is forced to '0 by hardware.*

Bit 14 Reserved, forced by hardware to 0.

Bit 13 **UE**: USART enable

When this bit is cleared the USART prescalers and outputs are stopped and the end of the current

byte transfer in order to reduce power consumption. This bit is set and cleared by software.

0: USART prescaler and outputs disabled

1: USART enabled

Bit 12 **M**: Word length

This bit determines the word length. It is set or cleared by software.

0: 1 Start bit, 8 Data bits, n Stop bit

1: 1 Start bit, 9 Data bits, n Stop bit

*Note: The M bit must not be modified during a data transfer (both transmission and reception)*

Bit 11 **WAKE**: Wakeup method

This bit determines the USART wakeup method, it is set or cleared by software.

0: Idle Line

1: Address Mark

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software.

Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled

1: Parity control enabled

Bit 9 **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.

- 0: Even parity
- 1: Odd parity

Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An USART interrupt is generated whenever PE=1 in the USART\_SR register

Bit 7 **TXEIE**: TXE interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An USART interrupt is generated whenever TXE=1 in the USART\_SR register

Bit 6 **TCIE**: Transmission complete interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An USART interrupt is generated whenever TC=1 in the USART\_SR register

Bit 5 **RXNEIE**: RXNE interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An USART interrupt is generated whenever ORE=1 or RXNE=1 in the USART\_SR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An USART interrupt is generated whenever IDLE=1 in the USART\_SR register

Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

- 0: Transmitter is disabled
- 1: Transmitter is enabled

*Note:* 1: During transmission, a "0" pulse on the TE bit ("0" followed by "1") sends a preamble (idle line) after the current word, except in smartcard mode.

2: When TE is set there is a 1 bit-time delay before the transmission starts.

**Bit 2 RE:** Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled

1: Receiver is enabled and begins searching for a start bit

**Bit 1 RWU:** Receiver wakeup

This bit determines if the USART is in mute mode or not. It is set and cleared by software and can be cleared by hardware when a wakeup sequence is recognized.

0: Receiver in active mode

1: Receiver in mute mode

*Note: 1: Before selecting Mute mode (by setting the RWU bit) the USART must first receive a data byte, otherwise it cannot function in Mute mode with wakeup by Idle line detection.*

*2: In Address Mark Detection wakeup configuration (WAKE bit=1) the RWU bit cannot be modified by software while the RXNE bit is set.*

**Bit 0 SBK:** Send break

This bit set is used to send break characters. It can be set and cleared by software. It should be set by software, and will be reset by hardware during the stop bit of break.

0: No break character is transmitted

1: Break character will be transmitted

### 23.6.5 Control register 2 (USART\_CR2)

Address offset: 0x10

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	LINEN	STOP[1:0]		CLKEN	CPOL	CPHA	LBCL	Res.	LBDIE	LBDL	Res.	ADD[3:0]			
	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, forced by hardware to 0.

Bit 14 **LINEN**: LIN mode enable

This bit is set and cleared by software.

0: LIN mode disabled

1: LIN mode enabled

The LIN mode enables the capability to send LIN Synch Breaks (13 low bits) using the SBK bit in the USART\_CR1 register, and to detect LIN Sync breaks.

Bits 13:12 **STOP**: STOP bits

These bits are used for programming the stop bits.

00: 1 Stop bit

01: 0.5 Stop bit

10: 2 Stop bits

11: 1.5 Stop bit

Bit 11 **CLKEN**: Clock enable

This bit allows the user to enable the SCLK pin.

0: SCLK pin disabled

1: SCLK pin enabled

Bit 10 **CPOL**: Clock polarity

This bit allows the user to select the polarity of the clock output on the SCLK pin in synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship

0: Steady low value on SCLK pin outside transmission window

1: Steady high value on SCLK pin outside transmission window

Bit 9 **CPHA**: Clock phase

This bit allows the user to select the phase of the clock output on the SCLK pin in synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see figures 191 to 192)

0: The first clock transition is the first data capture edge

1: The second clock transition is the first data capture edge

Bit 8 **LBCL**: Last bit clock pulse

This bit allows the user to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the SCLK pin in synchronous mode.

0: The clock pulse of the last data bit is not output to the SCLK pin

1: The clock pulse of the last data bit is output to the SCLK pin

1: The last bit is the 8th or 9th data bit transmitted depending on the 8 or 9 bit format selected by the M bit in the USART\_CR1 register.

Bit 7 Reserved, forced by hardware to 0.

Bit 6 **LBDIE**: LIN break detection interrupt enable  
 Break interrupt mask (break detection using break delimiter).  
 0: Interrupt is inhibited  
 1: An interrupt is generated whenever LBD=1 in the USART\_SR register

Bit 5 **LBDL**: *lin* break detection length  
 This bit is for selection between 11 bit or 10 bit break detection.  
 0: 10-bit break detection  
 1: 11-bit break detection

Bit 4 Reserved, forced by hardware to 0.

Bits 3:0 **ADD[3:0]**: Address of the USART node  
 This bit-field gives the address of the USART node.  
 This is used in multiprocessor communication during mute mode, for wake up with address mark detection.

*Note:* These 3 bits (CPOL, CPHA, LBCL) should not be written while the transmitter is enabled.

### 23.6.6 Control register 3 (USART\_CR3)

Address offset: 0x14

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				ONEBITE	CTSIE	CTSE	RTSE	DMAT	DMAR	SCEN	NACK	HDSEL	IRLP	IREN	EIE
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, forced by hardware to 0.

Bit 11 **ONEBITE**: One sample bit method enable  
 This bit allows the user to select the sample method. When the one sample bit method is selected the noise detection flag (NF) is disabled.  
 0: Three sample bit method  
 1: One sample bit method

Bit 10 **CTSIE**: CTS interrupt enable  
 0: Interrupt is inhibited  
 1: An interrupt is generated whenever CTS=1 in the USART\_SR register

Bit 9 **CTSE**: CTS enable  
 0: CTS hardware flow control disabled  
 1: CTS mode enabled, data is only transmitted when the nCTS input is asserted (tied to 0). If the nCTS input is deasserted while a data is being transmitted, then the transmission is completed before stopping. If a data is written into the data register while nCTS is asserted, the transmission is postponed until nCTS is asserted.

Bit 8 **RTSE**: RTS enable  
 0: RTS hardware flow control disabled  
 1: RTS interrupt enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The nRTS output is asserted (tied to 0) when a data can be received.

- Bit 7 **DMAT**: DMA enable transmitter  
This bit is set/reset by software  
1: DMA mode is enabled for transmission  
0: DMA mode is disabled for transmission
- Bit 6 **DMAR**: DMA enable receiver  
This bit is set/reset by software  
1: DMA mode is enabled for reception  
0: DMA mode is disabled for reception
- Bit 5 **SCEN**: Smartcard mode enable  
This bit is used for enabling Smartcard mode.  
0: Smartcard Mode disabled  
1: Smartcard Mode enabled
- Bit 4 **NACK**: Smartcard NACK enable  
0: NACK transmission in case of parity error is disabled  
1: NACK transmission during parity error is enabled
- Bit 3 **HDSEL**: Half-duplex selection  
Selection of Single-wire Half-duplex mode  
0: Half duplex mode is not selected  
1: Half duplex mode is selected
- Bit 2 **IRLP**: IrDA low-power  
This bit is used for selecting between normal and low-power IrDA modes  
0: Normal mode  
1: Low-power mode
- Bit 1 **IREN**: IrDA mode enable  
This bit is set and cleared by software.  
0: IrDA disabled  
1: IrDA enabled
- Bit 0 **EIE**: Error interrupt enable  
Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NF=1 in the USART\_SR register) in case of Multi Buffer Communication (DMAR=1 in the USART\_CR3 register).  
0: Interrupt is inhibited  
1: An interrupt is generated whenever DMAR=1 in the USART\_CR3 register and FE=1 or ORE=1 or NF=1 in the USART\_SR register.

### 23.6.7 Guard time and prescaler register (USART\_GTPR)

Address offset: 0x18

Reset value: 0x0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GT[7:0]								PSC[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, forced by hardware to 0.

Bits 15:8 **GT[7:0]**: Guard time value

This bit-field gives the Guard time value in terms of number of baud clocks.

This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value.

Bits 7:0 **PSC[7:0]**: Prescaler value

– In IrDA Low-power mode:

**PSC[7:0]** = IrDA Low-Power Baud Rate

Used for programming the prescaler for dividing the system clock to achieve the low-power frequency:

The source clock is divided by the value given in the register (8 significant bits):

00000000: Reserved - do not program this value

00000001: divides the source clock by 1

00000010: divides the source clock by 2

...

– In normal IrDA mode: PSC must be set to 00000001.

– In smartcard mode:

**PSC[4:0]**: Prescaler value

Used for programming the prescaler for dividing the system clock to provide the smartcard clock.

The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:

00000: Reserved - do not program this value

00001: divides the source clock by 2

00010: divides the source clock by 4

00011: divides the source clock by 6

...

*Note: 1: Bits [7:5] have no effect if Smartcard mode is used.*

### 23.6.8 USART register map

The table below gives the USART register map and reset values.

**Table 96. USART register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0x18	USART_GTPR	Reserved														GT[7:0]						PSC[7:0]																	
	Reset value															0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0							

Refer to [Table 1 on page 32](#) for the register boundary addresses.

## 24 Debug support (DBG)

### 24.1 Overview

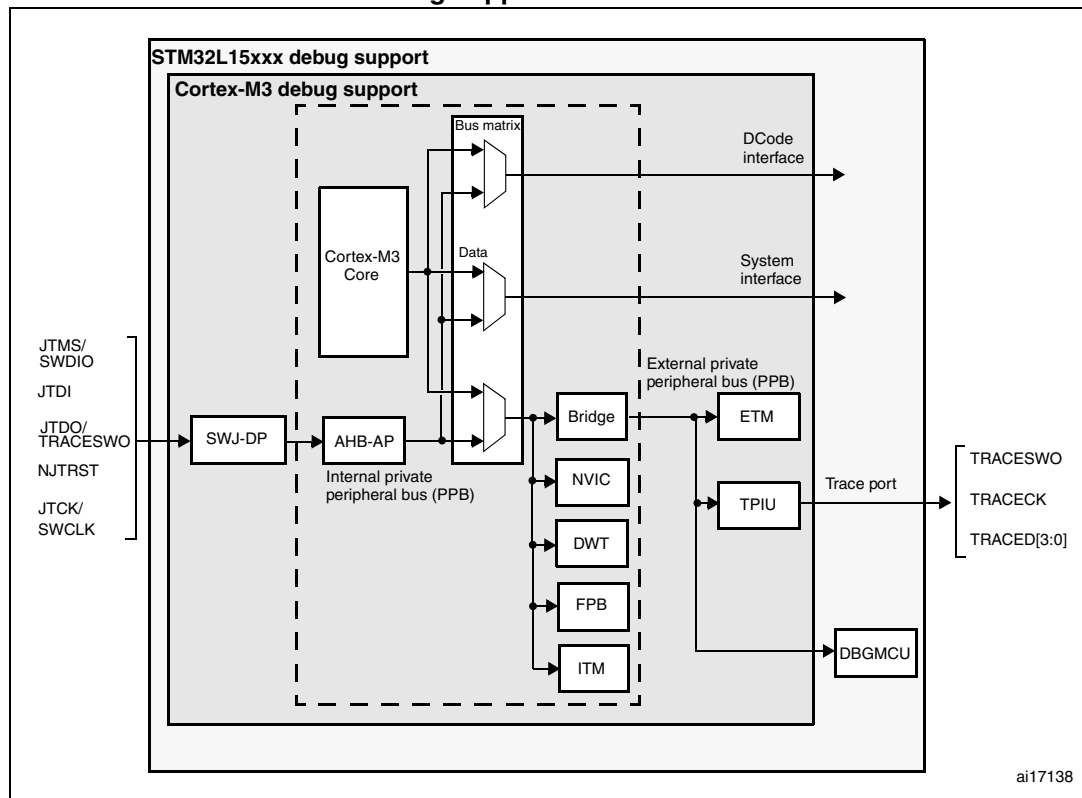

The STM32L15xxx are built around a Cortex-M3 core which contains hardware extensions for advanced debugging features. The debug extensions allow the core to be stopped either on a given instruction fetch (breakpoint) or data access (watchpoint). When stopped, the core's internal state and the system's external state may be examined. Once examination is complete, the core and the system may be restored and program execution resumed.

The debug features are used by the debugger host when connecting to and debugging the STM32L15xxx MCUs.

Two interfaces for debug are available:

- Serial wire
- JTAG debug port

**Figure 204. Block diagram of STM32L15xxx-level and Cortex-M3-level debug support**

*Note:* The debug features embedded in the Cortex-M3 core are a subset of the ARM CoreSight Design Kit.

The ARM Cortex-M3 core provides integrated on-chip debug support. It is comprised of:

- SWJ-DP: Serial wire / JTAG debug port
- AHP-AP: AHB access port
- ITM: Instrumentation trace macrocell
- FPB: Flash patch breakpoint
- DWT: Data watchpoint trigger
- TPUI: Trace port unit interface (available on larger packages, where the corresponding pins are mapped)
- ETM: Embedded Trace Macrocell (available on larger packages, where the corresponding pins are mapped)

It also includes debug features dedicated to the STM32L15xxx:

- Flexible debug pinout assignment
- MCU debug box (support for low-power modes, control over peripheral clocks, etc.)

*Note:* For further information on debug functionality supported by the ARM Cortex-M3 core, refer to the Cortex-M3-r2p0 Technical Reference Manual and to the CoreSight Design Kit-r2p0 TRM (see [Section 24.2: Reference ARM documentation](#)).

## 24.2 Reference ARM documentation

- Cortex™-M3 r2p0 Technical Reference Manual (TRM)  
(see Related documents on page 1)
- ARM Debug Interface V5
- ARM CoreSight Design Kit revision r2p0 Technical Reference Manual

## 24.3 SWJ debug port (serial wire and JTAG)

The STM32L15xxx core integrates the Serial Wire / JTAG Debug Port (SWJ-DP). It is an ARM standard CoreSight debug port that combines a JTAG-DP (5-pin) interface and a SW-DP (2-pin) interface.

- The JTAG Debug Port (JTAG-DP) provides a 5-pin standard JTAG interface to the AHP-AP port.
- The Serial Wire Debug Port (SW-DP) provides a 2-pin (clock + data) interface to the AHP-AP port.

In the SWJ-DP, the two JTAG pins of the SW-DP are multiplexed with some of the five JTAG pins of the JTAG-DP.

Figure 205. SWJ debug port

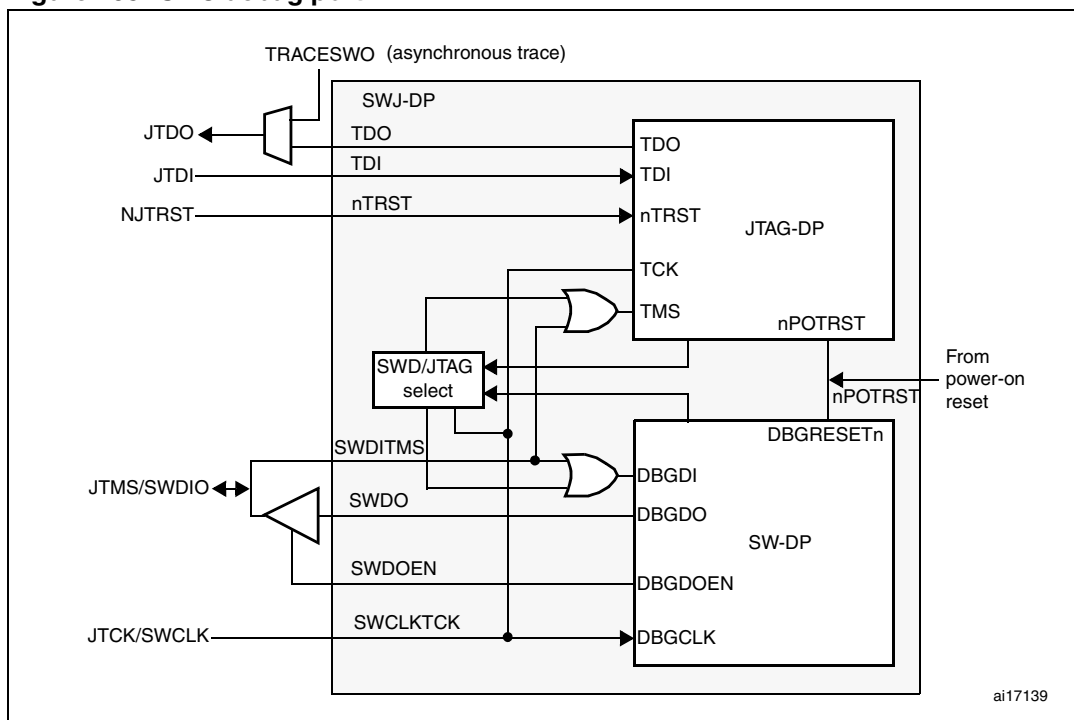

Figure 205 shows that the asynchronous TRACE output (TRACESWO) is multiplexed with TDO. This means that the asynchronous trace can only be used with SW-DP, not JTAG-DP.

### 24.3.1 Mechanism to select the JTAG-DP or the SW-DP

By default, the JTAG-Debug Port is active.

If the debugger host wants to switch to the SW-DP, it must provide a dedicated JTAG sequence on TMS/TCK (respectively mapped to SWDIO and SWCLK) which disables the JTAG-DP and enables the SW-DP. This way it is possible to activate the SWDP using only the SWCLK and SWDIO pins.

This sequence is:

1. Send more than 50 TCK cycles with TMS (SWDIO) =1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111100111100111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) =1

## 24.4 Pinout and debug port pins

The STM32L15xxx MCUs are available in various packages with different numbers of available pins. As a result, some functionality (ETM) related to pin availability may differ between packages.

### 24.4.1 SWJ debug port pins

Five pins are used as outputs from the STM32L15xxx for the SWJ-DP as *alternate functions* of general-purpose IOs. These pins are available on all packages.

**Table 97. SWJ debug port pins**

SWJ-DP pin name	JTAG debug port		SW debug port		Pin assignment
	Type	Description	Type	Debug assignment	
JTMS/SWDIO	I	JTAG Test Mode Selection	IO	Serial Wire Data Input/Output	PA13
JTCK/SWCLK	I	JTAG Test Clock	I	Serial Wire Clock	PA14
JTDI	I	JTAG Test Data Input	-	-	PA15
JTDO/TRACESWO	O	JTAG Test Data Output	-	TRACESWO if async trace is enabled	PB3
NJTRST	I	JTAG Test nReset	-	-	PB4

### 24.4.2 Flexible SWJ-DP pin assignment

After RESET (SYSRESETn or PORESETn), all five pins used for the SWJ-DP are assigned as dedicated pins immediately usable by the debugger host (note that the trace outputs are not assigned except if explicitly programmed by the debugger host).

However, the STM32L15xxx MCU offers the possibility of disabling some or all of the SWJ-DP ports and so, of releasing the associated pins for general-purpose IO (GPIO) usage. For more details on how to disable SWJ-DP port pins, please refer to [Section 24.4.2: Flexible SWJ-DP pin assignment](#).

**Table 98. Flexible SWJ-DP pin assignment**

Available debug ports	SWJ IO pin assigned				
	PA13 / JTMS / SWDIO	PA14 / JTCK / SWCLK	PA15 / JTDI	PB3 / JTDO	PB4 / NJTRST
Full SWJ (JTAG-DP + SW-DP) - Reset State	X	X	X	X	X
Full SWJ (JTAG-DP + SW-DP) but without NJTRST	X	X	X	X	
JTAG-DP Disabled and SW-DP Enabled	X	X			
JTAG-DP Disabled and SW-DP Disabled	Released				

**Note:** When the APB bridge write buffer is full, it takes one extra APB cycle when writing the GPIO\_AFR register. This is because the deactivation of the JTAGSW pins is done in two cycles to guarantee a clean level on the nTRST and TCK input signals of the core.

- Cycle 1: the JTAGSW input signals to the core are tied to 1 or 0 (to 1 for nTRST, TDI and TMS, to 0 for TCK)
- Cycle 2: the GPIO controller takes the control signals of the SWJTAG IO pins (like controls of direction, pull-up/down, Schmitt trigger activation, etc.).

### 24.4.3 Internal pull-up and pull-down on JTAG pins

It is necessary to ensure that the JTAG input pins are not floating since they are directly connected to flip-flops to control the debug mode features. Special care must be taken with the SWCLK/TCK pin which is directly connected to the clock of some of these flip-flops.

To avoid any uncontrolled IO levels, the device embeds internal pull-ups and pull-downs on the JTAG input pins:

- NJTRST: Internal pull-up
- JTDI: Internal pull-up
- JTMS/SWDIO: Internal pull-up
- TCK/SWCLK: Internal pull-down

Once a JTAG IO is released by the user software, the GPIO controller takes control again. The reset states of the GPIO control registers put the IOs in the equivalent state:

- NJTRST: Input pull-up
- JTDI: Input pull-up
- JTMS/SWDIO: Input pull-up
- JTCK/SWCLK: Input pull-down
- JTDO: Input floating

The software can then use these IOs as standard GPIOs.

*Note: The JTAG IEEE standard recommends to add pull-ups on TDI, TMS and nTRST but there is no special recommendation for TCK. However, for JTCK, the device needs an integrated pull-down.*

*Having embedded pull-ups and pull-downs removes the need to add external resistors.*

#### 24.4.4 Using serial wire and releasing the unused debug pins as GPIOs

To use the serial wire DP to release some GPIOs, the user software must change the GPIO (PA15, PB3 and PB4) configuration mode in the GPIO\_MODER register. This releases PA15, PB3 and PB4 which now become available as GPIOs.

When debugging, the host performs the following actions:

- Under system reset, all SWJ pins are assigned (JTAG-DP + SW-DP).
- Under system reset, the debugger host sends the JTAG sequence to switch from the JTAG-DP to the SW-DP.
- Still under system reset, the debugger sets a breakpoint on vector reset.
- The system reset is released and the Core halts.
- All the debug communications from this point are done using the SW-DP. The other JTAG pins can then be reassigned as GPIOs by the user software.

*Note:* For user software designs, note that:

*To release the debug pins, remember that they will be first configured either in input-pull-up ( $nTRST$ ,  $TMS$ ,  $TDI$ ) or pull-down ( $TCK$ ) or output tristate ( $TDO$ ) for a certain duration after reset until the instant when the user software releases the pins.*

*When debug pins (JTAG or SW or TRACE) are mapped, changing the corresponding IO pin configuration in the IOPORT controller has no effect.*

### 24.5 STM32L15xxx JTAG TAP connection

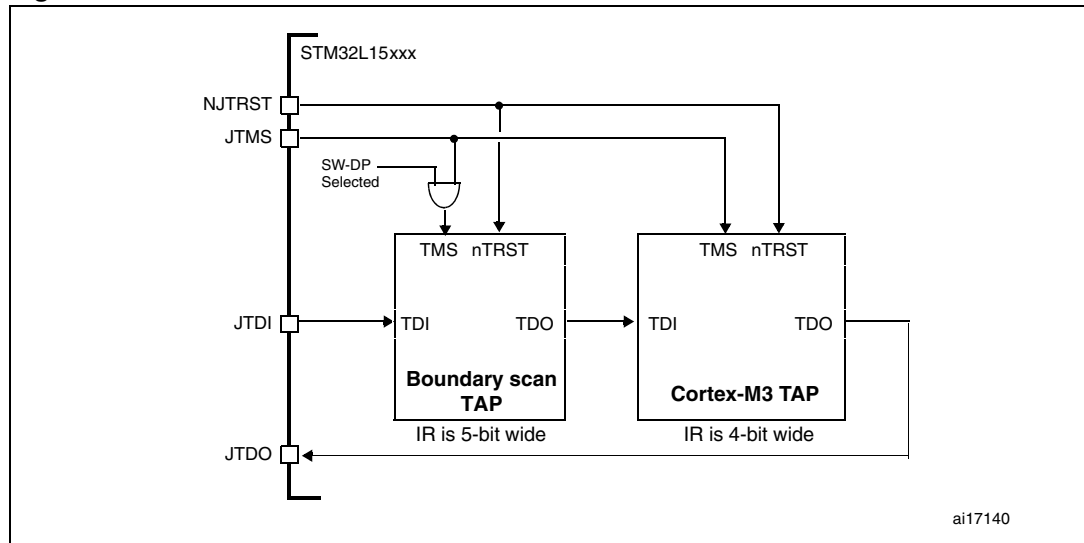

The STM32L15xxx MCUs integrate two serially connected JTAG TAPs, the boundary scan TAP (IR is 5-bit wide) and the Cortex-M3 TAP (IR is 4-bit wide).

To access the TAP of the Cortex-M3 for debug purposes:

1. First, it is necessary to shift the BYPASS instruction of the boundary scan TAP.
2. Then, for each IR shift, the scan chain contains 9 bits (=5+4) and the unused TAP instruction must be shifted in using the BYPASS instruction.
3. For each data shift, the unused TAP, which is in BYPASS mode, adds 1 extra data bit in the data scan chain.

*Note:* **Important:** Once Serial-Wire is selected using the dedicated ARM JTAG sequence, the boundary scan TAP is automatically disabled (JTMS forced high).

Figure 206. JTAG TAP connections

## 24.6 ID codes and locking mechanism

There are several ID codes inside the STM32L15xxx MCUs. ST strongly recommends tools designers to lock their debuggers using the MCU DEVICE ID code located in the external PPB memory map at address 0xE0042000.

### 24.6.1 MCU device ID code

The STM32L15xxx MCUs integrate an MCU ID code. This ID identifies the ST MCU part-number and the die revision. It is part of the DBG\_MCU component and is mapped on the external PPB bus (see [Section 24.16 on page 580](#)). This code is accessible using the JTAG debug port (4 to 5 pins) or the SW debug port (two pins) or by the user software. It is even accessible while the MCU is under system reset.

#### DBGMCU\_IDCODE

Address: 0xE0042000

Only 32-bits access supported. Read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
REV_ID																
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Reserved				DEV_ID												
				r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **REV\_ID(15:0)** Revision identifier

This field indicates the revision of the device:

- 0x1000 = Revision A
- 0x1008 = Revision Y

Bits 15:12 Reserved

Bits 11:0 **DEV\_ID(11:0)**: Device identifier  
 This field indicates the device ID.  
 The device ID is 0x416

## 24.6.2 Boundary scan TAP

### JTAG ID code

The TAP of the STM32L15xxx BSC (boundary scan) integrates a JTAG ID code equal to 0x06416041 0x4BA00477.

## 24.6.3 Cortex-M3 TAP

The TAP of the ARM Cortex-M3 integrates a JTAG ID code. This ID code is the ARM default one and has not been modified. This code is only accessible by the JTAG Debug Port. This code is **0x4BA00477** (corresponds to Cortex-M3 r2p0, see [Section 24.2: Reference ARM documentation](#)).

Only the DEV\_ID(11:0) should be used for identification by the debugger/programmer tools.

## 24.6.4 Cortex-M3 JEDEC-106 ID code

The ARM Cortex-M3 integrates a JEDEC-106 ID code. It is located in the 4KB ROM table mapped on the internal PPB bus at address 0xE00FF000\_0xE00FFFFF.

This code is accessible by the JTAG Debug Port (4 to 5 pins) or by the SW Debug Port (two pins) or by the user software.

## 24.7 JTAG debug port

A standard JTAG state machine is implemented with a 4-bit instruction register (IR) and five data registers (for full details, refer to the *Cortex-M3 r2p0 Technical Reference Manual (TRM)*, for references, please see [Section 24.2: Reference ARM documentation](#)).

**Table 99. JTAG debug port data registers**

0x8	10	DP SELECT register: Used to select the current access port and the active 4-words register window. – Bits 31:24: APSEL: select the current AP – Bits 23:8: reserved – Bits 7:4: APBANKSEL: select the active 4-words register window on the current AP – Bits 3:0: reserved
0xC	11	DP RDBUFF register: Used to allow the debugger to get the final result after a sequence of operations (without requesting new JTAG-DP operation)

## 24.8 SW debug port

### 24.8.1 SW protocol introduction

This synchronous serial protocol uses two pins:

- SWCLK: clock from host to target
- SWDIO: bidirectional

The protocol allows two banks of registers (DPACC registers and APACC registers) to be read and written to.

Bits are transferred LSB-first on the wire.

For SWDIO bidirectional management, the line must be pulled-up on the board (100 K $\Omega$  recommended by ARM).

Each time the direction of SWDIO changes in the protocol, a turnaround time is inserted where the line is not driven by the host nor the target. By default, this turnaround time is one bit time, however this can be adjusted by configuring the SWCLK frequency.

### 24.8.2 SW protocol sequence

Each sequence consist of three phases:

1. Packet request (8 bits) transmitted by the host
2. Acknowledge response (3 bits) transmitted by the target
3. Data transfer phase (33 bits) transmitted by the host or the target

**Table 101. Packet request (8-bits)**

Bit	Name	Description
0	Start	Must be "1"
1	APnDP	0: DP Access 1: AP Access
2	RnW	0: Write Request 1: Read Request

**Table 101. Packet request (8-bits) (continued)**

Bit	Name	Description
4:3	A(3:2)	Address field of the DP or AP registers (refer to <a href="#">Table 100</a> )
5	Parity	Single bit parity of preceding bits
6	Stop	0
7	Park	Not driven by the host. Must be read as “1” by the target because of the pull-up

Refer to the *Cortex-M3 r2p0 TRM* for a detailed description of DPACC and APACC registers.

The packet request is always followed by the turnaround time (default 1 bit) where neither the host nor target drive the line.

**Table 102. ACK response (3 bits)**

Bit	Name	Description
0..2	ACK	001: FAULT 010: WAIT 100: OK

The ACK Response must be followed by a turnaround time only if it is a READ transaction or if a WAIT or FAULT acknowledge has been received.

**Table 103. DATA transfer (33 bits)**

Bit	Name	Description
0..31	WDATA or RDATA	Write or Read data
32	Parity	Single parity of the 32 data bits

The DATA transfer must be followed by a turnaround time only if it is a READ transaction.

### 24.8.3 SW-DP state machine (reset, idle states, ID code)

The State Machine of the SW-DP has an internal ID code which identifies the SW-DP. It follows the JEP-106 standard. This ID code is the default ARM one and is set to 0x4BA00477 (corresponding to Cortex-M3 r2p0).

*Note:* Note that the SW-DP state machine is inactive until the target reads this ID code.

- The SW-DP state machine is in RESET STATE either after power-on reset, or after the DP has switched from JTAG to SWD or after the line is high for more than 50 cycles
- The SW-DP state machine is in IDLE STATE if the line is low for at least two cycles after RESET state.
- After RESET state, it is **mandatory** to first enter into an IDLE state AND to perform a READ access of the DP-SW ID CODE register. Otherwise, the target will issue a FAULT acknowledge response on another transactions.

Further details of the SW-DP state machine can be found in the *Cortex-M3 r2p0 TRM* and the *CoreSight Design Kit r2p0 TRM*.

#### 24.8.4 DP and AP read/write accesses

- Read accesses to the DP are not posted: the target response can be immediate (if ACK=OK) or can be delayed (if ACK=WAIT).
- Read accesses to the AP are posted. This means that the result of the access is returned on the next transfer. If the next access to be done is NOT an AP access, then the DP-RDBUFF register must be read to obtain the result.  
The READOK flag of the DP-CTRL/STAT register is updated on every AP read access or RDBUFF read request to know if the AP read access was successful.
- The SW-DP implements a write buffer (for both DP or AP writes), that enables it to accept a write operation even when other transactions are still outstanding. If the write buffer is full, the target acknowledge response is "WAIT". With the exception of IDCODE read or CTRL/STAT read or ABORT write which are accepted even if the write buffer is full.
- Because of the asynchronous clock domains SWCLK and HCLK, two extra SWCLK cycles are needed after a write transaction (after the parity bit) to make the write effective internally. These cycles should be applied while driving the line low (IDLE state)  
This is particularly important when writing the CTRL/STAT for a power-up request. If the next transaction (requiring a power-up) occurs immediately, it will fail.

#### 24.8.5 SW-DP registers

Access to these registers are initiated when APnDP=0

**Table 104. SW-DP registers**

A(3:2)	R/W	CTRLSEL bit of SELECT register	Register	Notes
00	Read		IDCODE	The manufacturer code is not set to ST code. 0x4BA00477 (identifies the SW-DP)
00	Write		ABORT	
01	Read/Write	0	DP-CTRL/STAT	Purpose is to: <ul style="list-style-type: none"> <li>– request a system or debug power-up</li> <li>– configure the transfer operation for AP accesses</li> <li>– control the pushed compare and pushed verify operations.</li> <li>– read some status flags (overrun, power-up acknowledges)</li> </ul>
01	Read/Write	1	WIRE CONTROL	Purpose is to configure the physical serial port protocol (like the duration of the turnaround time)
10	Read		READ RESEND	Enables recovery of the read data from a corrupted debugger transfer, without repeating the original AP transfer.

**Table 104. SW-DP registers (continued)**

A(3:2)	R/W	CTRLSEL bit of SELECT register	Register	Notes
10	Write		SELECT	The purpose is to select the current access port and the active 4-words register window
11	Read/Write		READ BUFFER	This read buffer is useful because AP accesses are posted (the result of a read AP request is available on the next AP transaction). This read buffer captures data from the AP, presented as the result of a previous read, without initiating a new transaction

### 24.8.6 SW-AP registers

Access to these registers are initiated when APnDP=1

There are many AP Registers (see AHB-AP) addressed as the combination of:

- The shifted value A[3:2]
- The current value of the DP SELECT register

## 24.9 AHB-AP (AHB access port) - valid for both JTAG-DP and SW-DP

### Features:

- System access is independent of the processor status.
- Either SW-DP or JTAG-DP accesses AHB-AP.
- The AHB-AP is an AHB master into the Bus Matrix. Consequently, it can access all the data buses (Dcode Bus, System Bus, internal and external PPB bus) but the ICode bus.
- Bitband transactions are supported.
- AHB-AP transactions bypass the FPB.

The address of the 32-bits AHP-AP registers are 6-bits wide (up to 64 words or 256 bytes) and consists of:

- c) Bits [7:4] = the bits [7:4] APBANKSEL of the DP SELECT register
- d) Bits [3:2] = the 2 address bits of A(3:2) of the 35-bit packet request for SW-DP.

The AHB-AP of the Cortex-M3 includes 9 x 32-bits registers:

**Table 105. Cortex-M3 AHB-AP registers**

Address offset	Register name	Notes
0x00	AHB-AP Control and Status Word	Configures and controls transfers through the AHB interface (size, hprot, status on current transfer, address increment type)
0x04	AHB-AP Transfer Address	
0x0C	AHB-AP Data Read/Write	
0x10	AHB-AP Banked Data 0	Directly maps the 4 aligned data words without rewriting the Transfer Address Register.
0x14	AHB-AP Banked Data 1	
0x18	AHB-AP Banked Data 2	
0x1C	AHB-AP Banked Data 3	
0xF8	AHB-AP Debug ROM Address	Base Address of the debug interface
0xFC	AHB-AP ID Register	

Refer to the *Cortex-M3 r2p0 TRM* for further details.

## 24.10 Core debug

Core debug is accessed through the core debug registers. Debug access to these registers is by means of the *Advanced High-performance Bus (AHB-AP)* port. The processor can access these registers directly over the internal *Private Peripheral Bus (PPB)*.

It consists of 4 registers:

**Table 106. Core debug registers**

Register	Description
DHCSR	<i>The 32-bit Debug Halting Control and Status Register</i> This provides status information about the state of the processor enable core debug halt and step the processor
DCRSR	<i>The 17-bit Debug Core Register Selector Register:</i> This selects the processor register to transfer data to or from.
DCRDR	<i>The 32-bit Debug Core Register Data Register:</i> This holds data for reading and writing registers to and from the processor selected by the DCRSR (Selector) register.
DEMCR	<i>The 32-bit Debug Exception and Monitor Control Register:</i> This provides Vector Catching and Debug Monitor Control. This register contains a bit named <b>TRCENA</b> which enable the use of a TRACE.

**Note:** ***Important:** these registers are not reset by a system reset. They are only reset by a power-on reset.*

Refer to the *Cortex-M3 r2p0 TRM* for further details.

To Halt on reset, it is necessary to:

- enable the bit0 (VC\_CORRESET) of the Debug and Exception Monitor Control Register
- enable the bit0 (C\_DEBUGEN) of the Debug Halting Control and Status Register.

## 24.11 Capability of the debugger host to connect under system reset

The STM32L15xxx MCUs' reset system comprises the following reset sources:

- POR (power-on reset) which asserts a RESET at each power-up.
- Internal watchdog reset
- Software reset
- External reset

The Cortex-M3 differentiates the reset of the debug part (generally PORRESETn) and the other one (SYSRESETn)

This way, it is possible for the debugger to connect under System Reset, programming the Core Debug Registers to halt the core when fetching the reset vector. Then the host can release the system reset and the core will immediately halt without having executed any instructions. In addition, it is possible to program any debug features under System Reset.

*Note: It is highly recommended for the debugger host to connect (set a breakpoint in the reset vector) under system reset.*

## 24.12 FPB (Flash patch breakpoint)

The FPB unit:

- implements hardware breakpoints
- patches code and data from code space to system space. This feature gives the possibility to correct software bugs located in the Code Memory Space.

The use of a Software Patch or a Hardware Breakpoint is exclusive.

The FPB consists of:

- 2 literal comparators for matching against literal loads from Code Space and remapping to a corresponding area in the System Space.
- 6 instruction comparators for matching against instruction fetches from Code Space. They can be used either to remap to a corresponding area in the System Space or to generate a Breakpoint Instruction to the core.

## 24.13 DWT (data watchpoint trigger)

The DWT unit consists of four comparators. They are configurable as:

- a hardware watchpoint or
- a trigger to an ETM or
- a PC sampler or
- a data address sampler

The DWT also provides some means to give some profiling informations. For this, some counters are accessible to give the number of:

- Clock cycle
- Folded instructions
- Load store unit (LSU) operations
- Sleep cycles
- CPI (clock per instructions)
- Interrupt overhead

## 24.14 ITM (instrumentation trace macrocell)

### 24.14.1 General description

The ITM is an application-driven trace source that supports *printf* style debugging to trace *Operating System* (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets which can be generated as:

- **Software trace.** Software can write directly to the ITM stimulus registers to emit packets.
- **Hardware trace.** The DWT generates these packets, and the ITM emits them.
- **Time stamping.** Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M3 clock or the bit clock rate of the *Serial Wire Viewer* (SWV) output clocks the counter.

The packets emitted by the ITM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to TPIU) and then output the complete packets sequence to the debugger host.

The bit TRCEN of the Debug Exception and Monitor Control Register must be enabled before you program or use the ITM.

The SysTick timer clock is not stopped during the Stop mode debug (DBG\_STOP bit set). The counter keeps on being decremented and can generate interrupts if they are enabled

### 24.14.2 Time stamp packets, synchronization and overflow packets

Time stamp packets encode time stamp information, generic control and synchronization. It uses a 21-bit timestamp counter (with possible prescalers) which is reset at each time stamp packet emission. This counter can be either clocked by the CPU clock or the SWV clock.

A synchronization packet consists of 6 bytes equal to 0x80\_00\_00\_00\_00\_00 which is emitted to the TPIU as 00 00 00 00 00 80 (LSB emitted first).

A synchronization packet is a timestamp packet control. It is emitted at each DWT trigger.

For this, the DWT must be configured to trigger the ITM: the bit CYCCNTENA (bit0) of the DWT Control Register must be set. In addition, the bit2 (SYNCENA) of the ITM Trace Control Register must be set.

*Note:* If the SYNENA bit is not set, the DWT generates Synchronization triggers to the TPIU which will send only TPIU synchronization packets and not ITM synchronization packets.

An overflow packet consists is a special timestamp packets which indicates that data has been written but the FIFO was full.

**Table 107. Main ITM registers**

Address	Register	Details
@E0000FB0	ITM lock access	Write 0xC5ACCE55 to unlock Write Access to the other ITM registers
@E0000E80	ITM trace control	Bits 31-24 = Always 0
		Bits 23 = Busy
		Bits 22-16 = 7-bits ATB ID which identifies the source of the trace data.
		Bits 15-10 = Always 0
		Bits 9:8 = TSPrescale = Time Stamp Prescaler
		Bits 7-5 = Reserved
		Bit 4 = SWOENA = Enable SWV behavior (to clock the timestamp counter by the SWV clock).
		Bit 3 = DWTENA: Enable the DWT Stimulus
		Bit 2 = SYNCENA: this bit must be to 1 to enable the DWT to generate synchronization triggers so that the TPIU can then emit the synchronization packets.
		Bit 1 = TSENA (Timestamp Enable)
		Bit 0 = ITMENA: Global Enable Bit of the ITM
@E0000E40	ITM trace privilege	Bit 3: mask to enable tracing ports31:24
		Bit 2: mask to enable tracing ports23:16
		Bit 1: mask to enable tracing ports15:8
		Bit 0: mask to enable tracing ports7:0
@E0000E00	ITM trace enable	Each bit enables the corresponding Stimulus port to generate trace.
@E0000000- E000007C	Stimulus port registers 0-31	Write the 32-bits data on the selected Stimulus Port (32 available) to be traced out.

**Example of configuration**

To output a simple value to the TPIU:

- Configure the TPIU and assign TRACE IOs by configuring the DBGMCU\_CR (refer to [Section 24.17.2: TRACE pin assignment](#) and [Section 24.16.3: Debug MCU configuration register](#))
- Write 0xC5ACCE55 to the ITM Lock Access Register to unlock the write access to the ITM registers
- Write 0x00010005 to the ITM Trace Control Register to enable the ITM with Sync enabled and an ATB ID different from 0x00
- Write 0x1 to the ITM Trace Enable Register to enable the Stimulus Port 0
- Write 0x1 to the ITM Trace Privilege Register to unmask stimulus ports 7:0
- Write the value to output in the Stimulus Port Register 0: this can be done by software (using a printf function)

## 24.15 ETM (Embedded trace macrocell)

### 24.15.1 General description

The ETM enables the reconstruction of program execution. Data are traced using the Data Watchpoint and Trace (DWT) component or the Instruction Trace Macrocell (ITM) whereas instructions are traced using the Embedded Trace Macrocell (ETM).

The ETM transmits information as packets and is triggered by embedded resources. These resources must be programmed independently and the trigger source is selected using the Trigger Event Register (0xE0041008). An event could be a simple event (address match from an address comparator) or a logic equation between 2 events. The trigger source is one of the fourth comparators of the DWT module, The following events can be monitored:

- Clock cycle matching
- Data address matching

For more informations on the trigger resources refer to [Section 24.13: DWT \(data watchpoint trigger\)](#).

The packets transmitted by the ETM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to [Section 24.17: TPIU \(trace port interface unit\)](#)) and then outputs the complete packet sequence to the debugger host.

### 24.15.2 Signal protocol, packet types

This part is described in the chapter 7 ETMv3 Signal Protocol of the ARM IHI 0014N document.

### 24.15.3 Main ETM registers

For more information on registers refer to the chapter 3 of the ARM IHI 0014N specification.

**Table 108. Main ETM registers**

Address	Register	Details
0xE0041FB0	ETM Lock Access	Write 0xC5ACCE55 to unlock the write access to the other ETM registers.
0xE0041000	ETM Control	This register controls the general operation of the ETM, for instance how tracing is enabled.
0xE0041010	ETM Status	This register provides information about the current status of the trace and trigger logic.
0xE0041008	ETM Trigger Event	This register defines the event that will control trigger.
0xE004101C	ETM Trace Enable Control	This register defines which comparator is selected.
0xE0041020	ETM Trace Enable Event	This register defines the trace enabling event.
0xE0041024	ETM Trace Start/Stop	This register defines the traces used by the trigger source to start and stop the trace, respectively.

### 24.15.4 Configuration example

To output a simple value to the TPIU:

- Configure the TPIU and enable the I/O\_TRACEN to assign TRACE IOs in the XL- and high-density device's debug configuration register.
- Write 0xC5ACCE55 to the ETM Lock Access Register to unlock the write access to the ITM registers
- Write 0x00001D1E to the control register (configure the trace)
- Write 0000406F to the Trigger Event register (define the trigger event)
- Write 0000006F to the Trace Enable Event register (define an event to start/stop)
- Write 00000001 to the Trace Start/stop register (enable the trace)
- Write 0000191E to the ETM Control Register (end of configuration)

## 24.16 MCU debug component (DBGMCU)

The MCU debug component helps the debugger provide support for:

- Low-power modes
- Clock control for timers, watchdog (WWDG and IWDG) and I2Cs
- Control of the trace pins assignment

### 24.16.1 Debug support for low-power modes

To enter low-power mode, the instruction WFI or WFE must be executed.

The MCU implements several low-power modes which can either deactivate the CPU clock or reduce the power of the CPU.

The core does not allow FCLK or HCLK to be turned off during a debug session. As these are required for the debugger connection, during a debug, they must remain active. The MCU integrates special means to allow the user to debug software in low-power modes.

For this, the debugger host must first set some debug configuration registers to change the low-power mode behavior:

- In Sleep mode, DBG\_SLEEP bit of DBGMCU\_CR register must be previously set by the debugger. This will feed HCLK with the same clock that is provided to FCLK (system clock previously configured by the software).
- In Stop mode, the bit DBG\_STOP must be previously set by the debugger. This will enable the internal RC oscillator clock to feed FCLK and HCLK in STOP mode.

### 24.16.2 Debug support for timers, watchdog and I<sup>2</sup>C

During a breakpoint, it is necessary to choose how the counter of timers and watchdog should behave:

- They can continue to count inside a breakpoint. This is usually required when a PWM is controlling a motor, for example.
- They can stop to count inside a breakpoint. This is required for watchdog purposes.

For the I<sup>2</sup>C, the user can choose to block the SMBUS timeout during a breakpoint.

### 24.16.3 Debug MCU configuration register

This register allows the configuration of the MCU under DEBUG. This concerns:

- Low-power mode support: Sleep, Stop and Standby modes
- Trace pin assignment

This DBGMCU\_CR is mapped on the External PPB bus at address 0xE0042004

It is asynchronously reset by the PORESET (and not the system reset). It can be written by the debugger under system reset.

If the debugger host does not support these features, it is still possible for the user software to write to these registers.

#### DBGMCU\_CR

Address: 0xE004 2004

Only 32-bit access supported

POR Reset: 0x0000 0000 (not reset by system reset)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Reserved																
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved								TRACE_MODE [1:0]		TRACE_IOEN	Reserved			DBG_STANDBY	DBG_STOP	DBG_SLEEP
								rw	rw	rw				rw	rw	rw

Bits 31:8 Reserved, must be kept cleared.

Bits 7:5 **TRACE\_MODE[1:0] and TRACE\_IOEN**: Trace pin assignment control

– With *TRACE\_IOEN=0*:

TRACE\_MODE=xx: TRACE pins not assigned (default state)

– With *TRACE\_IOEN=1*:

- TRACE\_MODE=00: TRACE pin assignment for Asynchronous Mode
- TRACE\_MODE=01: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 1
- TRACE\_MODE=10: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 2
- TRACE\_MODE=11: TRACE pin assignment for Synchronous Mode with a TRACEDATA size of 4

Bits 4:3 Reserved, must be kept cleared.

Bit 2 **DBG\_STANDBY**: Debug Standby mode

0: (FCLK=Off, HCLK=Off) The whole digital part is unpowered.

From software point of view, exiting from Standby is identical than fetching reset vector (except a few status bit indicated that the MCU is resuming from Standby)

1: (FCLK=On, HCLK=On) In this case, the digital part is not unpowered and FCLK and HCLK are provided by the internal RC oscillator which remains active. In addition, the MCU generate a system reset during Standby mode so that exiting from Standby is identical than fetching from reset

Bit 1 **DBG\_STOP**: Debug Stop mode

0: (FCLK=Off, HCLK=Off) In STOP mode, the clock controller disables all clocks (including HCLK and FCLK). When exiting from STOP mode, the clock configuration is identical to the one after RESET (CPU clocked by the 8 MHz internal RC oscillator (HSI)). Consequently, the software must reprogram the clock controller to enable the PLL, the Xtal, etc.

1: (FCLK=On, HCLK=On) In this case, when entering STOP mode, FCLK and HCLK are provided by the internal RC oscillator which remains active in STOP mode. When exiting STOP mode, the software must reprogram the clock controller to enable the PLL, the Xtal, etc. (in the same way it would do in case of DBG\_STOP=0)

Bit 0 **DBG\_SLEEP**: Debug Sleep mode

0: (FCLK=On, HCLK=Off) In Sleep mode, FCLK is clocked by the system clock as previously configured by the software while HCLK is disabled.

In Sleep mode, the clock controller configuration is not reset and remains in the previously programmed state. Consequently, when exiting from Sleep mode, the software does not need to reconfigure the clock controller.

1: (FCLK=On, HCLK=On) In this case, when entering Sleep mode, HCLK is fed by the same clock that is provided to FCLK (system clock as previously configured by the software).

### 24.16.4 Debug MCU APB1 freeze register (DBGMCU\_APB1\_FZ)

The DBGMCU\_APB1\_FZ register is used to configure the MCU under DEBUG. It concerns the APB1 peripherals:

- Timer clock counter freeze
- I2C SMBUS timeout freeze
- Window watchdog and independent watchdog counter freeze support

This DBGMCU\_APB1\_FZ is mapped on the external PPB bus at address 0xE0042008.

The register is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address: 0xE004 2008

Only 32-bit access are supported.

Power on reset (POR): 0x0000 0000 (not reset by system reset)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Reserved			DBG_IWDG_STOP	DBG_WWDG_STOP	Reserved						DBG_TIM7_STOP	DBG_TIM6_STOP	Reserved	DBG_TIM4_STOP	DBG_TIM3_STOP	DBG_TIM2_STOP
			rw	rw							rw	rw		rw	rw	rw

Bits 31:23 Reserved

Bit 22 **DBG\_I2C2\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when core is halted  
 0: Same behavior as in normal mode  
 1: The SMBUS timeout is frozen

Bit 21 **DBG\_I2C1\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when core is halted  
 0: Same behavior as in normal mode  
 1: The SMBUS timeout is frozen

Bits 20:13 Reserved

Bit 12 **DBG\_IWDG\_STOP**: Debug independent watchdog stopped when core is halted  
 0: The independent watchdog counter clock continues even if the core is halted  
 1: The independent watchdog counter clock is stopped when the core is halted

Bit 11 **DBG\_WWDG\_STOP**: Debug window watchdog stopped when core is halted  
 0: The window watchdog counter clock continues even if the core is halted  
 1: The window watchdog counter clock is stopped when the core is halted

Bits 10:6 Reserved

Bit 5 **DBG\_TIM7\_STOP**: TIM7 counter stopped when core is halted  
 0: The counter clock of TIM7 is fed even if the core is halted  
 1: The counter clock of TIM7 is stopped when the core is halted

Bit 4 **DBG\_TIM6\_STOP**: TIM6 counter stopped when core is halted  
 0: The counter clock of TIM6 is fed even if the core is halted  
 1: The counter clock of TIM6 is stopped when the core is halted

Bit 3 Reserved

Bit 2 **DBG\_TIM4\_STOP**: TIM4 counter stopped when core is halted  
 0: The counter clock of TIM4 is fed even if the core is halted  
 1: The counter clock of TIM4 is stopped when the core is halted

Bit 1 **DBG\_TIM3\_STOP**: TIM3 counter stopped when core is halted  
 0: The counter clock of TIM3 is fed even if the core is halted  
 1: The counter clock of TIM3 is stopped when the core is halted

Bit 0 **DBG\_TIM2\_STOP**: TIM2 counter stopped when core is halted  
 0: The counter clock of TIM2 is fed even if the core is halted  
 1: The counter clock of TIM2 is stopped when the core is halted

### 24.16.5 Debug MCU APB2 freeze register (DBGMCU\_APB2\_FZ)

The DBGMCU\_APB2\_FZ register is used to configure the MCU under DEBUG. It concerns APB2 peripherals:

- Timer clock counter freeze

This register is mapped on the external PPB bus at address 0xE004 200C

It is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address: 0xE004 200C

Only 32-bit access is supported.

POR: 0x0000 0000 (not reset by system reset)

Bits 31:5 Reserved

Bits 4:2 **DBG\_TIMx\_STOP**: TIMx counter stopped when core is halted (x=9..11)

0: The clock of the involved timer counter is fed even if the core is halted

1: The clock of the involved timer counter is stopped when the core is halted

Bits 1:0 Reserved

## 24.17 TPIU (trace port interface unit)

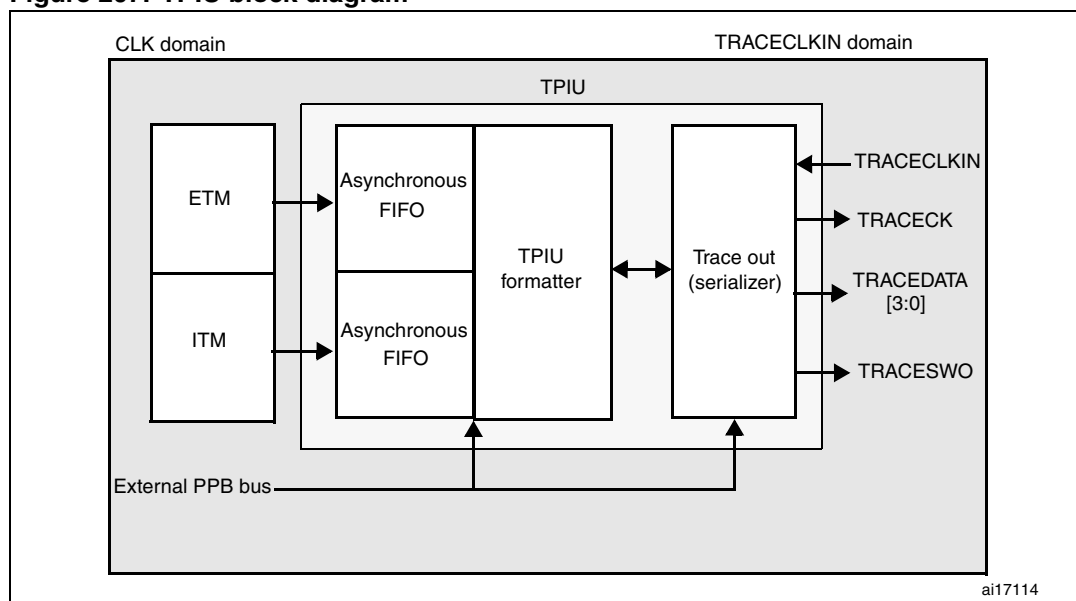

### 24.17.1 Introduction

The TPIU acts as a bridge between the on-chip trace data from the ITM and the ETM.

The output data stream encapsulates the trace source ID, that is then captured by a *trace port analyzer* (TPA).

The core embeds a simple TPIU, especially designed for low-cost debug (consisting of a special version of the CoreSight TPIU).

Figure 207. TPIU block diagram

### 24.17.2 TRACE pin assignment

- Asynchronous mode  
The asynchronous mode requires 1 extra pin and is available on all packages. It is only available if using Serial Wire mode (not in JTAG mode).

Table 109. Asynchronous TRACE pin assignment

TPIU pin name	Trace synchronous mode		STM32L15xxx pin assignment
	Type	Description	
TRACESWO	O	TRACE Async Data Output	PB3

- Synchronous mode  
The synchronous mode requires from 2 to 6 extra pins depending on the data trace size and is only available in the larger packages. In addition it is available in JTAG mode and in Serial Wire mode and provides better bandwidth output capabilities than asynchronous trace.

**Table 110. Synchronous TRACE pin assignment**

TPUI pin name	Trace synchronous mode		STM32L15xxx pin assignment
	Type	Description	
TRACECK	O	TRACE Clock	PE2
TRACED[3:0]	O	TRACE Sync Data Outputs Can be 1, 2 or 4.	PE[6:3]

**TPUI TRACE pin assignment**

By default, these pins are NOT assigned. They can be assigned by setting the TRACE\_IOEN and TRACE\_MODE bits in the **MCU Debug component configuration register**. This configuration has to be done by the debugger host.

In addition, the number of pins to assign depends on the trace configuration (asynchronous or synchronous).

- **Asynchronous mode:** 1 extra pin is needed
- **Synchronous mode:** from 2 to 5 extra pins are needed depending on the size of the data trace port register (1, 2 or 4):
  - TRACECK
  - TRACED(0) if port size is configured to 1, 2 or 4
  - TRACED(1) if port size is configured to 2 or 4
  - TRACED(2) if port size is configured to 4
  - TRACED(3) if port size is configured to 4

To assign the TRACE pin, the debugger host must program the bits TRACE\_IOEN and TRACE\_MODE[1:0] of the Debug MCU configuration Register (DBGMCU\_CR). By default the TRACE pins are not assigned.

This register is mapped on the external PPB and is reset by the PORESET (and not by the SYSTEM reset). It can be written by the debugger under SYSTEM reset.

Table 111. Flexible TRACE pin assignment

DBGMCU_CR register		Pins assigned for:	TRACE IO pin assigned					
TRACE_IOEN	TRACE_MODE[1:0]		PB3 / JTDO / TRACESWO	PE2 / TRACECK	PE3 / TRACED[0]	PE4 / TRACED[1]	PE5 / TRACED[2]	PE6 / TRACED[3]
0	XX	No Trace (default state)	Released <sup>(1)</sup>					
1	00	Asynchronous Trace	TRACESWO			Released (usable as GPIO)		
1	01	Synchronous Trace 1 bit	Released <sup>(1)</sup>	TRACECK	TRACED[0]			
1	10	Synchronous Trace 2 bit		TRACECK	TRACED[0]	TRACED[1]		
1	11	Synchronous Trace 4 bit		TRACECK	TRACED[0]	TRACED[1]	TRACED[2]	TRACED[3]

1. When Serial Wire mode is used, it is released. But when JTAG is used, it is assigned to JTDO.

*Note:* By default, the TRACECLKIN input clock of the TPIU is tied to GND. It is assigned to HCLK two clock cycles after the bit TRACE\_IOEN has been set.

The debugger must then program the Trace Mode by writing the PROTOCOL[1:0] bits in the SPP\_R (Selected Pin Protocol) register of the TPIU.

- PROTOCOL=00: Trace Port Mode (synchronous)
- PROTOCOL=01 or 10: Serial Wire (Manchester or NRZ) Mode (asynchronous mode). Default state is 01

It then also configures the TRACE port size by writing the bits [3:0] in the CPSPS\_R (Current Sync Port Size Register) of the TPIU:

- 0x1 for 1 pin (default state)
- 0x2 for 2 pins
- 0x8 for 4 pins

### 24.17.3 TPUI formatter

The formatter protocol outputs data in 16-byte frames:

- seven bytes of data
- eight bytes of mixed-use bytes consisting of:
  - 1 bit (LSB) to indicate it is a DATA byte ('0) or an ID byte ('1).
  - 7 bits (MSB) which can be data or change of source ID trace.
- one byte of auxiliary bits where each bit corresponds to one of the eight mixed-use bytes:
  - if the corresponding byte was a data, this bit gives bit0 of the data.
  - if the corresponding byte was an ID change, this bit indicates when that ID change takes effect.

*Note:* Refer to the ARM CoreSight Architecture Specification v1.0 (ARM IHI 0029B) for further information

### 24.17.4 TPUI frame synchronization packets

The TPUI can generate two types of synchronization packets:

- The Frame Synchronization packet (or Full Word Synchronization packet)  
It consists of the word: 0x7F\_FF\_FF\_FF (LSB emitted first). This sequence can not occur at any other time provided that the ID source code 0x7F has not been used.  
It is output periodically **between** frames.  
In continuous mode, the TPA must discard all these frames once a synchronization frame has been found.
- The Half-Word Synchronization packet  
It consists of the half word: 0x7F\_FF (LSB emitted first).  
It is output periodically **between or within** frames.  
These packets are only generated in continuous mode and enable the TPA to detect that the TRACE port is in IDLE mode (no TRACE to be captured). When detected by the TPA, it must be discarded.

### 24.17.5 Transmission of the synchronization frame packet

There is no Synchronization Counter register implemented in the TPIU of the core. Consequently, the synchronization trigger can only be generated by the **DWT**. Refer to the registers DWT Control Register (bits SYNCTAP[11:10]) and the DWT Current PC Sampler Cycle Count Register.

The TPUI Frame synchronization packet (0x7F\_FF\_FF\_FF) is emitted:

- after each TPIU reset release. This reset is synchronously released with the rising edge of the TRACECLKIN clock. This means that this packet is transmitted when the TRACE\_IOEN bit in the DBGMCU\_CFG register is set. In this case, the word 0x7F\_FF\_FF\_FF is not followed by any formatted packet.
- at each DWT trigger (assuming DWT has been previously configured). Two cases occur:
  - If the bit SYNENA of the ITM is reset, only the word 0x7F\_FF\_FF\_FF is emitted without any formatted stream which follows.
  - If the bit SYNENA of the ITM is set, then the ITM synchronization packets will follow (0x80\_00\_00\_00\_00\_00), formatted by the TPUI (trace source ID added).

### 24.17.6 Synchronous mode

The trace data output size can be configured to 4, 2 or 1 pin: TRACED(3:0)

The output clock is output to the debugger (TRACECK)

Here, TRACECLKIN is driven internally and is connected to HCLK only when TRACE is used.

*Note:* In this synchronous mode, it is not required to provide a stable clock frequency.

The TRACE IOs (including TRACECK) are driven by the rising edge of TRACLKIN (equal to HCLK). Consequently, the output frequency of TRACECK is equal to HCLK/2.

### 24.17.7 Asynchronous mode

This is a low cost alternative to output the trace using only 1 pin: this is the asynchronous output pin TRACESWO. Obviously there is a limited bandwidth.

TRACESWO is multiplexed with JTDO when using the SW-DP pin. This way, this functionality is available in all STM32L15xxx packages.

This asynchronous mode requires a constant frequency for TRACECLKIN. For the standard UART (NRZ) capture mechanism, 5% accuracy is needed. The Manchester encoded version is tolerant up to 10%.

### 24.17.8 TRACECLKIN connection inside the STM32L15xxx

In the STM32L15xxx, this TRACECLKIN input is internally connected to HCLK. This means that when in asynchronous trace mode, the application is restricted to use to time frames where the CPU frequency is stable.

*Note:* **Important:** when using asynchronous trace: it is important to be aware that:

*The default clock of the STM32L15xxx MCUs is the internal RC oscillator. Its frequency under reset is different from the one after reset release. This is because the RC calibration is the default one under system reset and is updated at each system reset release.*

*Consequently, the trace port analyzer (TPA) should not enable the trace (with the TRACE\_IOEN bit) under system reset, because a Synchronization Frame Packet will be issued with a different bit time than trace packets which will be transmitted after reset release.*

### 24.17.9 TPIU registers

The TPIU APB registers can be read and written only if the bit TRCENA of the Debug Exception and Monitor Control Register (DEMCR) is set. Otherwise, the registers are read as zero (the output of this bit enables the PCLK of the TPIU).

**Table 112. Important TPIU registers**

Address	Register	Description
0xE0040004	Current port size	Allows the trace port size to be selected: Bit 0: Port size = 1 Bit 1: Port size = 2 Bit 2: Port size = 3, not supported Bit 3: Port Size = 4  Only 1 bit must be set. By default, the port size is one bit. (0x00000001)
0xE00400F0	Selected pin protocol	Allows the Trace Port Protocol to be selected: Bit1:0= 00: Sync Trace Port Mode 01: Serial Wire Output - manchester (default value) 10: Serial Wire Output - NRZ 11: reserved
0xE0040304	Formatter and flush control	Bit 31-9 = always '0 Bit 8 = TriglIn = always '1 to indicate that triggers are indicated Bit 7-4 = always 0 Bit 3-2 = always 0 Bit 1 = EnFCont. In Sync Trace mode (Select_Pin_Protocol register bit1:0=00), this bit is forced to '1: the formatter is automatically enabled in continuous mode. In asynchronous mode (Select_Pin_Protocol register bit1:0 <> 00), this bit can be written to activate or not the formatter. Bit 0 = always 0  The resulting default value is 0x102 <b>Note:</b> In synchronous mode, because the TRACECTL pin is not mapped outside the chip, the formatter is always enabled in continuous mode -this way the formatter inserts some control packets to identify the source of the trace packets).
0xE0040300	Formatter and flush status	Not used in Cortex-M3, always read as 0x00000008

### 24.17.10 Example of configuration

- Set the bit TRCENA in the Debug Exception and Monitor Control Register (DEMCR)
- Write the TPIU Current Port Size Register to the desired value (default is 0x1 for a 1-bit port size)
- Write TPIU Formatter and Flush Control Register to 0x102 (default value)
- Write the TPIU Select Pin Protocol to select the sync or async mode. Example: 0x2 for async NRZ mode (UART like)
- Write the DBGMCU control register to 0x20 (bit IO\_TRACEN) to assign TRACE IOs for async mode. A TPIU Sync packet is emitted at this time (FF\_FF\_FF\_7F)
- Configure the ITM and write the ITM Stimulus register to output a value

## 24.18 DBG register map

The following table summarizes the Debug registers.

**Table 113. DBG register map and reset values**

Addr.	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																					
0xE0042000	DBGMCU_IDCODE	REV_ID													Reserved				DEV_ID																																			
	Reset value <sup>(1)</sup>	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X					X	X	X	X	X	X	X	X	X	X	X	X																					
0xE0042004	DBGMCU_CR	Reserved																							TRACE_MODE [1:0]		TRACE_IOEN		Reserved			DBG_		DBG_		DBG_																		
	Reset value																								0	0	0																											
0xE0042008	DBGMCU_APB1_FZ	Reserved										DBG_I2C2_SMBUS_TIMEOUT		DBG_I2C1_SMBUS_TIMEOUT		Reserved				DBG_IWDG_STOP		DBG_WWDG_STOP		Reserved						DBG_TIM7_STOP		DBG_TIM6_STOP		Reserved			DBG_TIM4_STOP		DBG_TIM3_STOP		DBG_TIM2_STOP													
	Reset value											0	0					0	0							0	0				0	0	0	0	0	0	0	0	0	0	0	0												
0xE004200C	DBGMCU_APB2_FZ	Reserved																							DBG_TIM11_STOP		DBG_TIM10_STOP		Reserved			DBG_TIM9_STOP		Reserved																				
	Reset value																								0	0				0	0			0	0			0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. The reset value is product dependent. For more information, refer to [Section 24.6.1: MCU device ID code](#).

## 25 Device electronic signature

This section applies to all STM32L15xxx devices, unless otherwise specified.

The electronic signature is stored in the System memory area in the Flash memory module, and can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match its interface to the characteristics of the STM32L15xxx microcontroller.

### 25.1 Memory size register

#### 25.1.1 Flash size register

Base address: 0x1FF8004C

Read only = 0xXXXX where X is factory-programmed

Bits 15:0 **F\_SIZE**: Flash memory size

This field value indicates the Flash memory size of the device in Kbytes.

Example: 0x0080 = 128 Kbytes.

### 25.2 Unique device ID registers (96 bits)

The unique device identifier is ideally suited:

- for use as serial numbers
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes/half-words/words in different ways and then be concatenated using a custom algorithm.

**Base address: 0x1FF8 0050**

Address offset: 0x00

Read only = 0xXXXX where X is factory-programmed

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
U_ID(31:16)															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
U_ID(15:0)															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **U\_ID(31:0)**: 31:0 unique ID bits

Address offset: 0x04

Read only = 0xXXXX where X is factory-programmed

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
U_ID(63:48)

**Please Read Carefully:**

Information in this document is provided solely in connection with ST products. STMicroelectronics NV and its subsidiaries ("ST") reserve the right to make changes, corrections, modifications or improvements, to this document, and the products and services described herein at any time, without notice.

All ST products are sold pursuant to ST's terms and conditions of sale.

Purchasers are solely responsible for the choice, selection and use of the ST products and services described herein, and ST assumes no liability whatsoever relating to the choice, selection or use of the ST products and services described herein.

No license, express or implied, by estoppel or otherwise, to any intellectual property rights is granted under this document. If any part of this document refers to any third party products or services it shall not be deemed a license grant by ST for the use of such third party products or services, or any intellectual property contained therein or considered as a warranty covering the use in any manner whatsoever of such third party products or services or any intellectual property contained therein.

**UNLESS OTHERWISE SET FORTH IN ST'S TERMS AND CONDITIONS OF SALE ST DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY WITH RESPECT TO THE USE AND/OR SALE OF ST PRODUCTS INCLUDING WITHOUT LIMITATION IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE (AND THEIR EQUIVALENTS UNDER THE LAWS OF ANY JURISDICTION), OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.**

**UNLESS EXPRESSLY APPROVED IN WRITING BY AN AUTHORIZED ST REPRESENTATIVE, ST PRODUCTS ARE NOT RECOMMENDED, AUTHORIZED OR WARRANTED FOR USE IN MILITARY, AIR CRAFT, SPACE, LIFE SAVING, OR LIFE SUSTAINING APPLICATIONS, NOR IN PRODUCTS OR SYSTEMS WHERE FAILURE OR MALFUNCTION MAY RESULT IN PERSONAL INJURY, DEATH, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE. ST PRODUCTS WHICH ARE NOT SPECIFIED AS "AUTOMOTIVE GRADE" MAY ONLY BE USED IN AUTOMOTIVE APPLICATIONS AT USER'S OWN RISK.**

Resale of ST products with provisions different from the statements and/or technical features set forth in this document shall immediately void any warranty granted by ST for the ST product or service described herein and shall not create or extend in any manner whatsoever, any liability of ST.

ST and the ST logo are trademarks or registered trademarks of ST in various countries.

Information in this document supersedes and replaces all information previously supplied.

The ST logo is a registered trademark of STMicroelectronics. All other names are the property of their respective owners.
